Despite its high cure rates and tissue-sparing advantages, Mohs micrographic surgery (MMS) presents several notable disadvantages that limit its universal application. One of the primary concerns is the limited availability of specialized centers and trained personnel, making access difficult in under-resourced or rural healthcare settings. MMS is also more time-consuming than standard excision, as it involves intraoperative histological analysis of multiple tissue layers, requiring patients to remain in the facility for extended periods. Additionally, the procedure is costlier due to the need for specialized equipment and trained histopathologists, potentially placing a financial burden on healthcare systems and patients alike. From a logistical standpoint, not all lesions are suitable for MMS—tumors with extensive subclinical spread, poorly defined borders, or aggressive histologic subtypes may require complementary or alternative approaches. Lastly, in settings where rapid frozen-section pathology is not feasible, delays in diagnosis and treatment can occur, reducing the practicality of MMS outside high-volume dermatologic surgery centers [32]. While Mohs surgery offers excellent cure rates, its use in elderly patients requires careful consideration. The prolonged procedure time, need for patient immobility, and potential for postoperative care challenges may be poorly tolerated by those with comorbidities or cognitive impairment. Therefore, treatment should be individualized based on the patient's overall health, functional status, and life expectancy [33].

CONCLUSION

This study highlights the challenges of achieving adequate surgical margins in high-risk anatomical areas affected by nonmelanoma skin cancers. Although arbitrary margins based on surgeon experience averaged 5.4 mm, histopathological evaluation revealed that a significant number of excisions had suboptimal peripheral or deep clearance, particularly in constrained areas like the nose and scalp. Despite a 91.2% overall rate of complete excision, the 8.8% rate of positive margins underscores the limitations of visual and tactile margin estimation alone. The findings support existing guidelines recommending wider margins ≥5 mm for BCC and ≥6 mm for cSCC, while also emphasizing the need to balance oncologic safety with aesthetic and functional preservation. In high-risk regions, individualized surgical planning, improved intraoperative margin assessment, and consideration of techniques like Mohs micrographic surgery in selected cases may optimize outcomes and minimize recurrence. Ultimately, refining margin estimation and tailoring surgical strategy to both tumor characteristics and anatomical context are essential for improving the quality of care in patients with high-risk NMSCs.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Abstract: Cardiovascular-kidney-metabolic (CKM) syndrome describes the complex, bidirectional interplay among cardiovascular, renal, and metabolic dysfunctions, where impairment in one system accelerates decline in the others. This interconnected pathophysiology significantly elevates the risk and progression of heart disease, particularly heart failure, through mechanisms involving insulin resistance, systemic inflammation, neurohormonal activation, and endothelial dysfunction. In this context, therapeutic strategies targeting heart disease must address the multifaceted drivers of CKM. Recent advances highlight the need for an integrated, patient-centered approach that combines lifestyle interventions with pharmacological treatments tailored to individual cardiovascular risk. While foundational therapies such as RAAS inhibitors and statins remain essential, novel agents now offer additional prognostic and quality-of-life benefits. SGLT2 inhibitors have emerged as a cornerstone therapy, improving outcomes in heart failure with both preserved and reduced ejection fraction, independent of glycemic control. GLP-1 receptor agonists and dual GLP-1/GIP agonists like tirzepatide demonstrate cardiometabolic and renal protection, while finerenone shows promise in diabetic kidney disease and several heart failure phenotypes. These therapies not only target glycemic control but also reduce cardiovascular mortality, hospitalizations, and renal decline. Optimizing cardiovascular outcomes in CKM syndrome requires early, multifactorial therapeutic intervention, informed by evolving evidence and a deeper understanding of the heart–kidney–metabolism axis.

Keywords: heart failure, diabetes mellitus, obesity, chronic kidney disease, GLP-1 receptor agonists, SGLT2 inhibitors, mineralocorticoid-receptor antagonists, finerenone, cardiovascular-kidney-metabolic syndrome

INTRODUCTION

Heart disease is frequently observed in patients with CKM syndrome. There is a pathophysiological interplay between the cardiovascular, renal, and metabolic systems, where dysfunction in one organ can exacerbate impairment in others, which substantially increases the risk of developing heart failure. Patients with CKM syndrome usually present with overlapping conditions as type 2 diabetes, chronic kidney disease, and atherosclerotic cardiovascular disease, all of which contribute to functional and structural cardiac dysfunction.

Heart disease and cardiovascular mortality represent the main drivers of prognosis in all CKM syndrome comorbidities. Hence, special consideration should be directed toward understanding pathophysiological mechanisms through which all these metabolic risk factors converge toward cardiovascular impairment. Additionally, emphasis should be placed on the early and appropriate initiation of the right medication for the right patient, tailored to the estimated individual risk, particularly concerning the novel drug classes that have demonstrated beneficial effects across all components of the CKM syndrome: GLP1 receptor agonists, SGLT2 inhibitors, and the non-steroidal mineralocorticoid receptor antagonist finerenone.

This review emphasises the role of the heart in the CKM spectrum, with particular interest in the therapeutic implications.

GLP-1 RECEPTOR AGONISTS

GLP-1 (glucagon-like peptide-1) is a natural hormone mainly released by intestinal L enteroendocrine cells residing in the distal jejunum, ileum, and colon, as a result to oral glucose intake. GLP-1 is classified as an incretin hormone because it stimulates insulin release from beta pancreatic cells, inhibits the release of glucagon and, along with that, hepatic glucose output, and reduces the rate of gastric emptying and promotes satiety by central appetite suppression. GLP-1 has a very short half-life of approximately 2 minutes, being quickly cleaved by dipeptidyl peptidase IV (DPP-4), a widely expressed enzyme, thereby limiting the strong insulin secretagogue effect of this hormone [1–3].

Owing to the very short half-life, the molecule of GLP-1 is not suitable for an adequate therapeutic agent. Nevertheless, researchers developed molecules capable of being adequate therapeutic agents: inhibitors of DPP-4, which are capable of prolonging the effects of natural GLP-1, and molecules that represent long-acting GLP-1 receptor agonists [1].

Apart from pancreas, GLP-1 receptors are expressed on various types of cells throughout the body and the finding of this widespread localization of receptors led to studies that demonstrated multiple effects beyond the well-known incretin actions, the so-called “pleiotropic effects”: in central nervous system, being involved in the regulation of appetite, in the cardiovascular system, being expressed both in cardiomyocytes and vascular cells, in the musculoskeletal system, gastrointestinal tract, regulating the motility or secretion, interfering in the gut-brain axis, in adipose tissue influencing fat metabolism through interaction with leptin, in kidneys at multiple levels (arterial and arteriolar smooth cells, glomerulus, juxtaglomerular cells, proximal tubule), modulating renal function both directly by altering glomerular hemodynamics and indirectly through less known direct interactions between gastrointestinal system and kidneys known as gut-renal axis [3–7]. Even in beta pancreatic cells, besides altering insulin or glucagon levels, the stimulation of GLP-1R could enhance beta-cell proliferation, inhibit apoptotic pathways, and induce expansion of islet mass [4].

Considering that diabetes mellitus and obesity serve as risk factors in the context of cardiovascular diseases, the effects of GLP-1 receptor agonists on the cardiovascular system are, to a considerable extent, mediated through modulation of these metabolic conditions.

Regarding their role as antidiabetic medications, all GLP-1RAs proved effective in glycemic control by reliably reducing fasting plasma glucose and HbA1c (up to a reduction of 56.2 mg/dl FPG levels and 2.1% for HbA1c levels, respectively) [8].

Obesity is strongly associated with the development of T2DM as excessive adipose tissue, particularly visceral fat, contributes to insulin resistance [9]. The central downregulation of appetite, accompanied by slowing the gastric evacuation, which induces a feeling of fullness, facilitates the reduction of overall calorie intake and the maintenance of a favorable long-term energy balance [3]. Large meta-analyses of the available RCTs proved that GLP-1 RA are effective in inducing weight loss and a reduction in the body mass index and in the waist circumference [8,10].

Conversely, an increasing body of evidence suggests that GLP-1RAs exert direct beneficial effects on various components of the cardiovascular system, independently of their impact on glycemic regulation and weight control.

As far as cardiomyocytes are concerned, the presence and the exact extent of GLP-1R expression are unclear, corroborated by limited evidence regarding the cellular localization of GLP-1R protein [11]. However, in cellular and animal models, besides metabolic effects, which could indirectly improve cardiac function, there is evidence that GLP-1 could restore crucial signaling pathways that could be altered by external stressors [7]. For example, GLP-1 could ameliorate the extent of ischemia-reperfusion injury by activating specific signaling pathways and inhibiting cardiomyocyte apoptosis [3]. Moreover, GLP-1 signaling is involved in reducing hyperglycemia-induced apoptosis of the cardiomyocytes by optimizing the signaling pathways from the sarcoplasmic reticulum and in lowering the extracellular matrix remodeling [12].

There is also important evidence that GLP-1 receptor stimulation influences various pathogenic mechanisms that are involved in atherogenesis. First of all, GLP-1 can mitigate endothelial dysfunction by inducing NOS-mediated vasodilation and by limiting the formation of advanced glycosylation end-products [3,13]. Additionally, GLP-1 is involved in improving lipid metabolism at several levels: with respect to gene expression, it downregulates genes of lipogenic enzymes and upregulates genes of lipolytic enzymes, reduces lipotoxicity by lowering lipid peroxidation, stimulates fatty acid oxygenation, inhibits HMG-CoA reductase and lowers cholesterol levels, ameliorates hepatic steatosis, lowers serum triglyceride levels and even reduces intestinal lipid absorption [3,14]. There are also described effects of enhanced cholesterol efflux from foam cells or suppression of foam cell formation [13]. Even an anti-inflammatory pathway is proposed with the downregulation of genes involved in inflammation and oxidative stress. Moreover, GLP-1 promotes an atherosclerotic plaque remodeling towards stabilization by reduction of matrix metalloproteinases (MMP), proteolytic enzymes involved in weakening of plaque fibrous caps and in increasing the risk of rupture [3,13].

GLP-1RA proved effects of blood pressure reduction both in preclinical and clinical studies, by as much as 6 mmHg (as it was found in DURATION-1 trial) [11,15]. There are several mechanisms possibly involved in this effect: the capacity of GLP-1RA to counteract the sympathetic nervous system hyperactivation, both at the central and peripheral nervous system level, the improvement in the endothelial function and therefore in vasodilation, and the possible effect on renal tubular mechanisms by increased natriuresis, which was observed in experimental models of hypertension [16,17]. The effect of lowering blood pressure was consistent throughout the entire spectrum of renal function, from normal to severely reduced [18].

Diabetes affected individuals are at high risk of chronic kidney disease (CKD) (as many as 40% diabetic patients develop chronic kidney disease), diabetic nephropathy representing the leading cause of chronic kidney disease worldwide. However, in the CKD population, cardiovascular events constitute the primary contributor to mortality, due to enhanced atherosclerosis, arterial and valvular calcification, and amplification of myocardial fibrosis [19]. There is a clear rationale that reducing both the risk and progression of chronic kidney disease could play a pivotal role in decreasing the burden of cardiovascular complications in diabetic patients.

Apart from indirect beneficial effects of glycemic control, weight loss and blood pressure reduction upon renal function, there are described direct effects: increased natriuresis and diuresis, at least partially explained by inhibiting sodium-hydrogen exchanger 3 in proximal tubular cells, anti-inflammatory effects by inhibition of cytokine production and chemotactic recruitment of inflammatory cells, free-radical scavenging effects and direct glomerular hemodynamic effects [5,17,19].

Another pathophysiological mechanism seemingly targeted by this therapeutic class is the modulation of the renin–angiotensin–aldosterone system, as there was been proven that GLP-1RA could induce a decrease in plasma levels of renin and angiotensin II. The effect of lowering the activity of this system could contribute to the effect of lowering blood pressure, the enhanced natriuresis, and could influence glomerular hemodynamics by vasodilation of the efferent arteriole and reduction of glomerular capillary pressure [18].

Beyond the pathophysiological effects demonstrated at the experimental level, the clinically relevant renoprotective effects include the reduction of albuminuria and, as evidenced by several studies, a reduction in eGFR decline [18,20].

Transitioning from experimental models and pathophysiological mechanisms to clinical evidence, GLP-1RA use in practice is supported by results from representative large-scale cardiovascular outcome trials. These studies have positioned GLP-1 receptor agonists as a distinct class among antidiabetic medications, with benefits that go beyond mere glycemic regulation.

There are 8 cardiovascular outcomes randomized controlled trials (CVOTs) for 7 different GLP-1RA (lixisenatide, liraglutide, semaglutide s.c., oral semaglutide, exenatide, albiglutide, dulaglutide, efpeglenatide) which included type 2 diabetic patients with high cardiovascular risk or previous cardiovascular disease. Four different GLP-1RAs, namely liraglutide, semaglutide s.c., dulaglutide, and efpeglenatide, proved efficient in reducing a composite end-point of major adverse cardiac events MACE (comprising cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke)[21]. However, analyzing the hazard ratio for individual components of MACE, there is a clear heterogeneity between these molecules. A meta-analysis which included all 8 RCTs, comprising a total of 60.080 patients (72.4% having established cardiovascular disease), concluded that GLP-1RA class reduce MACE by 14% (HR = 0.86, 95% CI 0.79-0.94, P = 0.006), with significant effects on the risk of cardiovascular death by 13% (P = 0.016) and nonfatal stroke by 16% (P = 0.007) [22]. Another meta-analysis, which included the same RCTs but ELIXA (the RCT examining lixisenatide), because lixisenatide is a short-acting agent that raised concerns regarding the lack of sustained GLP-1 inhibition in patients, GLP-1 RA proved effective in reducing MACE by 14% (HR 0.86 [95% CI 0.80–0.93]; p<0.0001), cardiovascular death by 13% (HR 0.87 [0.80–0.94]; p=0.0010), stroke by 17% (0.83 [0.76–0.92; p=0.0002), and, in addition to the other meta-analysis, myocardial infarction by 10% (0.90 [0.83–0.98]; p=0.020) [23]. Additionally, both meta-analyses proved a significant 12% reduction in all-cause mortality [22,23].

Table 1: Major CVOTs of GLP-1RA [21] (Although promising results, albiglutide was withdrawn from the market by the manufacturer due to commercial reasons)

Taking into account the various pleiotropic effects of GLP-1, there has emerged the hypothetical idea of using GLP-1RA in individuals without diabetes. In 2023, the results of the SELECT trial were published, a randomized controlled trial that included overweight patients (BMI>27 kg/m^2) with a history of cardiovascular disease but without diabetes. Subcutaneous semaglutide proved efficient, compared to placebo, in reducing MACE by 20% (HR 0.80 [0.72 to 0.90]; p<0.001), mainly driven by a statistically significant reduction of myocardial infarction risk by 28% [24].

These solid results, from large, reputable RCTs, have been translated into guideline recommendations. According to the 2024 ESC Guidelines for the management of chronic coronary syndromes and the 2023 ESC Guidelines for the management of cardiovascular disease in patients with diabetes, GLP-1RAs have a class I (level of evidence A) recommendation in patients with diabetes mellitus type 2 and history of atherosclerotic cardiovascular disease to reduce incident MACE [25,26]. This recommendation stands regardless of the baseline or target HbA1c or any other antidiabetic medications the patient may be taking. Additionally, consistent with the SELECT trial, the 2024 ESC Guidelines for the management of chronic coronary syndromes (CCS) included a IIa (level of evidence B) recommendation for the utilization of subcutaneous semaglutide in overweight (BMI > 27 kg/m^2) CCS patients to mitigate the risk of cardiovascular mortality and myocardial infarction [24,25].

As far as kidney outcomes are concerned, there is an RCT specifically designed to assess renal endpoints. The FLOW trial included 3533 patients with type 2 diabetes mellitus and CKD (defined as eGFR 50-75 ml/min/1.73m^2 and macroalbuminuria UACR >300 mg/g or eGFR 25-50 ml/min/1.73m^2 and albuminuria UACR >100 mg/g) and compared subcutaneous semaglutide with placebo. The results showed that subcutaneous semaglutide reduced the risk of a primary outcome (defined as a composite of major renal adverse events comprising new onset of kidney failure, a reduction of eGFR of at least 50% from baseline, or death from kidney or cardiovascular-related causes) with 24% (HR 0.76; [0.66 to 0.88]; p=0.0003) [27]. There is also some evidence toward improving kidney outcomes emerging from the pivotal CVOTs of GLP-1RA and from the meta-analyses which assessed them, but with a lower degree of statistical power as the conclusions are derived from secondary outcomes or exploratory assessments, and the renal benefits were demonstrated through the reduction in the progression of albuminuria, with fewer effects observed on hard end-points [21].

With regard to heart failure, the aforementioned meta-analyses reported a 10% risk reduction of heart failure hospitalizations, but this result was driven only by the reduction reported in the AMPLITUDE-O trial, which investigated efpeglenatide [21–23]. As a result, this outcome could not be generalized as a class effect.

2 clinical trials specifically investigated GLP-1RA in HFrEF patients: FIGHT and LIVE. Neither of the two trials demonstrated the beneficial effects of GLP-1 receptor agonists in patients with HFrEF. Notably, the LIVE trial even raised concerns regarding a potential trend toward an increased risk of mortality, ventricular arrhythmias, and atrial fibrillation [21,28]. In terms of HFpEF, two complementary RCTs were published, which investigated subcutaneous semaglutide in obese patients (BMI>30 kg/m^2) without DM (STEP-HFpEF) and with DM (STEP-HFpEF DM). In both trials, there are reported similar results: significant reductions in primary end-points such as a reduction of 7.8 points in Kansas City Cardiomyopathy Questionnaire (KCCQ) (95% CI [4.8 to 10.9]; P<0.001) in STEP-HFpEF and a reduction of 7.3 points in KCCQ in STEP-HFpEF DM (95% [CI] [4.1 to 10.4]; P<0.001) and an average of 10.7% reduction in body weight (95% CI [−11.9 to −9.4]; P<0.001) in STEP-HFpEF and 6.4% reduction in body weight (95% CI [−7.6 to −5.2]; P<0.001) in STEP-HFpEF DM. There are also reported significant results concerning secondary end-points, such as an average improvement of 20.3 m at 6-minute walk distance (95% CI [8.6 to 32.1]; P<0.001) in STEP-HFpEF and 14.3 m (95% CI [3.7 to 24.9]; P=0.008] in STEP-HFpEF DM, respectively. Essentially, these two trials proved that semaglutide improves symptoms and exercise capacity in obese HFpEF patients with or without type 2 DM, but neither study was powered enough to evaluate the influence on hard clinical events, such as heart failure-related hospitalizations or urgent hospital visits [29,30]. It has been suggested that the clear weight reduction effect had a major contribution to the improvement of symptoms and exercise capacity in these patients [21].

Tirzepatide has recently emerged as a new star in the GLP-1 modulation field, being the latest discovered molecule in this class. More specifically, tirzepatide is a dual agonist that acts both on the receptors of GLP-1 and the receptors of GIP (glucose-dependent insulinotropic polypeptide). GIP represents another incretin hormone, naturally released by K-cells of the upper small intestine. Tirzepatide was validated as an effective antidiabetic medication (up to 2.4% reduction in HbA1c), as proved in the series of trials SURPASS 1-5, when tirzepatide was subsequently compared to placebo, or to active comparators, such as semaglutide, to which it was shown to be non-inferior or insulin degludec, to which it was shown to be superior in terms of glycemic control [31]. In terms of weight management, in SURMOUNT 1-4 clinical trials, tirzepatide proved a potent effect, with a mean weight loss of up to 26% [32]. In a recent network meta-analysis, compared to GLP-1 RA, tirzepatide proved higher efficacy in terms of glycemic control and weight control, probably owing to the dual incretin action [8]

Besides direct effects in the metabolic pathway, the SUMMIT trial yielded noteworthy findings in both the cardiovascular and, to some extent, the renal pathways of CKM syndrome. It included 731 obese patients (BMI over 30 kg/m^2) with HFpEF (LVEF of at least 50%), regardless of their diabetes status, who were randomized to receive either tirzepatide or placebo. The trial yielded positive results with regard to the both primary end-points: first one representing a composite end-point formed by death from cardiovascular causes or a worsening heart failure event (hazard ratio, 0.62; 95% confidence interval [CI], 0.41 to 0.95; P=0.026), a result mainly driven by a reduction in worsening heart-failure events (hazard ratio, 0.54; 95% CI, 0.34 to 0.85), and the second one a reduction in KCCQ score, with a between-group difference at the end of the study of 6.9 (95% CI [3.3 to 10.6]; P<0.001). There was no difference in cardiovascular death [33]. Therefore, for the first time, the SUMMIT trial offered evidence derived from an RCT that influencing metabolic pathways with tirzepatide, regardless of diabetes diagnosis, we could influence hard cardiovascular end-points.

An interesting, recently published subanalysis of the SUMMIT trial found that the beneficial effects of tirzepatide upon worsening heart failure events or various metrics pertaining to functional capacity or quality of life are not influenced by the presence or absence of CKD, namely, eGFR does not seem to influence the effects on major adverse heart failure outcomes. In a head-to-head comparison pertaining to the primary composite end-point of death from cardiovascular causes or a worsening heart failure event, tirzepatide showed a larger absolute risk reduction in the CKD group (preventing 3.6 primary endpoint events for 100 patients treated for 1 year) compared to the group without CKD (preventing 1.6 primary endpoint events for 100 patients treated for 1 year). This may probably be an effect at least partially explained by the larger global risk of heart failure events in CKD patients. Moreover, tirzepatide seems to significantly ameliorate glomerular function at 52 weeks (+2.9 [95% CI: 0.9-4.9]; P = 0.004), an effect which proved constant throughout the broad spectrum of baseline eGFR (between 15 ml/min/1.73 m^2 and 70 ml/min/1.73m^2), as well as UACR at 24 weeks (−25%; 95% CI: −35.5% to −12.7%; P < 0.001) [34].

Although we have a very probable class effect of GLP-1RA in reducing MACE and unique evidence for tirzepatide in influencing hard end-points in HFpEF, currently, there is no direct evidence from RCTs that the dual GLP-1R/GIPR agonist reduces MACE. There exists an ongoing trial (SURPASS-CVOT) which currently evaluates the effect of tirzepatide in comparison to dulaglutide on MACE in patients with type 2 diabetes mellitus.

In general, GLP-1RAs are considered relatively well-tolerated medications, and evidence derived from clinical trials supports their effectiveness. However, there are described side effects such as hypersensitivity reactions (including, in rare cases, anaphylactic shock), a hypothetical enhanced risk of C-cell thyroid neoplasm (based on animal studies and theoretical risk), gastrointestinal adverse effects (such as nausea or vomiting, especially during initiation or dose escalation, increased ileus risk), an increased risk of cholelithiasis, cholecystitis and pancreatitis, and concerns of increased pancreatic cancer risk emerging from observational studies. Generally, gastrointestinal adverse effects are the most common and the most frequent cause of drug discontinuation [35].

SGLT2 INHIBITORS

SGLT2 inhibitors were created to target the SGLT2 transporter, a protein mainly located in the first segment of the proximal convoluted tubule, which is responsible for the absorption of 90-97% of the filtered glucose. The reabsorption of one molecule of glucose is coupled with one sodium ion, the latter being transported along the transmembrane concentration gradient created by the Na/K ATP-ase pump [36]. The residual glucose that escapes reabsorption is transported via SGLT1, which is located in the more distal parts of the proximal convoluted tubule. In case of SGLT2 blockage, SGLT1 could partially compensate for its effects, with only 50-60% of the filtered glucose excreted in the urine [37]. Although SGLT2 is mainly located in the kidney, it is also found in the brain, liver, thyroid, and striated muscle [36,37].

The development of SGLT2 inhibitors was inspired by phlorizin, a naturally occurring compound known to be a SGLT2 inhibitor, with the therapeutic objective of promoting natriuresis and glycosuria in order to obtain glycemic control [37]. In the context of efforts to preserve the biologically active properties of phlorizin, while also improving its oral bioavailability and stability, a series of novel molecules were developed: canagliflozin, dapagliflozin, empagliflozin, and ertugliflozin. Moreover, a dual inhibitor that blocks both SGLT1/SGLT2, namely sotagliflozin, was approved, which adds the effect of delaying intestinal glucose absorption by inhibiting SGLT1 at this level [37,38]. All molecules share very attractive pharmacologic properties: optimal oral absorption, once-daily administration as a result of the long half-life, metabolism occurring primarily in the liver, reduced renal clearance, and absence of clinically significant drug interactions [37].

Throughout studies, SGLT2 inhibitors have shown only modest effectiveness with regard to glycemic control, with reductions in HbA1c levels within the range of 0.5-1% [36,39]. Despite continuous glycosuria, inhibition of SGLT2 reduces insulin release and increases glucagon levels, which stimulates gluconeogenesis besides activation of lipolysis and lipid oxidation [40]. Similar to GLP-1 receptor agonists, and constituting an important observation for the largely overweight type 2 diabetes population, it was observed that SGLT2 inhibitors also exert a weight-reducing effect. This effect was observed to be approximately 2 to 4 kg, a consistent and durable reduction documented across all studies and for all molecules. To refer to specific figures, the inhibition of glucose reabsorption at the nephron level causes a loss of 75 g of glucose per day, which means nearly 300 kcal per day. It would be expected that a yearly weight loss of 10 kg, which is much more than was noted in clinical studies [40]. There are proposed mechanisms for this discrepancy between theory and practice, and the most prominent one is compensatory hyperphagia induced by a reduction in leptin, a hormone released by adipose tissue which inhibits appetite at a central level [40,41].

After the finding that rosiglitazone, a thiazolidinedione, is associated with an increased risk of adverse cardiovascular events, the scientific community requested that the new SGLT2i need to undergo cardiovascular outcome trials in order to prove their safety, similar to the aforementioned GLP-1RA.

The EMPA-REG OUTCOME trial tested empagliflozin in over 7000 patients with established cardiovascular disease and proved that this SLGT2i is associated with a significant 14% (HR 0.86; 95% confidence interval [CI], 0.74–0.99; p=0.04) reduction in the risk of major adverse cardiovascular events, a 32% reduction of all-cause mortality (HR, 0.68; 95% CI, 0.57–0.82]; p<0.001), and a 35% reduction of HF hospitalization risk (HR, 0.65; 95% CI, 0.50–0.85; p=0.002) [42,43]. Similarly, the DECLARE TIMI trial, for dapagliflozin, showed non-inferiority to placebo with respect to MACE (p<0.001) and a reduction with 17% of the risk for cardiovascular death or hospitalization for heart failure (HR, 0.83; 95% CI, 0.73-0.95; p=0.005) [42,44]. The CANVAS trial, for canagliflozin, showed a reduction with 14% of the combined risk of death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke (HR, 0.86; 95% CI, 0.75 to 0.97; P<0.001 for noninferiority; P=0.02 for superiority) [42,45]. Ultimately, the VERTIS trial, which studied ertugliflozin, found a significant reduction in the risk of heart failure hospitalizations [42]. Based on these preliminary studies, the ESC guidelines for the management of heart failure mention a class I indication for the utilization of SGLT2i in diabetic patients at high risk for CV events to reduce the risk of hospitalization for heart failure events, MACE, end-stage renal dysfunction, or cardiovascular death [46].

These initial trials prompted the conduction of future dedicated trials in order to establish a potential role of SGLT2i in the management of heart failure patients.

The further DAPA-HF trial proved to be a pivotal study, which paved the way for the actual large indications of SGLT2i in heart failure with reduced ejection fraction (HFrEF). This trial included 4744 patients with II-IV HYHA class heart failure, with an ejection fraction of less than 40% and proved that dapagliflozin (10 mg single dose) is associated with the reduction of a primary composite outcome of cardiovascular death, HF hospitalizations, and worsening HF (HR, 0.74; 95% CI, 0.65 to 0.85; P<0.001), with all components of this composite outcome being positively and significantly influenced. This trial also found that the effect is not influenced by the diabetic status of the patient [42,47].

For empagliflozin, the EMPEROR-Reduced trial showed similar results: a reduced composite outcome of cardiovascular death and HF hospitalizations (HR, 0.75; 95% CI, 0.65–0.86; p<0.001), similarly independent of the diabetic status of the patient. In the case of empagliflozin, the effect on the primary outcome was mainly driven by the reduction of the rate of HF hospitalizations, as the reduction of cardiovascular death proved to be non-significant [42,48]. A meta-analysis of these 2 landmark trials found significant reductions in all-cause death (pooled HR 0.87, 95% CI 0.77-0.98; p=0.018) and in cardiovascular death (pooled HR 0.86, 0.76-0.98; p=0.027) [49].

These findings have been incorporated into guideline recommendations, as both the ESC guidelines and the ACC/AHA guidelines on heart failure mention dapagliflozin and empagliflozin as indicated in all HFrEF patients, irrespective of their diabetic status, to reduce the risk of heart failure-related death or hospitalization (class I level of recommendation A) [46,50].

Encouraged by the positive results in the HFrEF field and taking into account the lack of available medications with prognostic effects in HFpEF, the idea of investigating the efficacy of these medications in this prevalent HF phenotype has emerged. And initial evidence emerged from the SOLOIST-WHF trial, which evaluated the effects of sotagliflozin, the dual SGLT1/SGLT2 inhibitor, initiated soon after an episode of decompensation of heart failure; sotagliflozin proved a lower risk of a primary composite end-point formed by cardiovascular death or hospitalizations and urgent visits for heart failure (HR, 0.67; 95% confidence interval [CI], 0.52 to 0.85; P<0.001). The result, suggesting a potential effect of SGLT2i in HFpEF, was that the risk reduction of the primary end-point was consistent across the entire spectrum of ejection fraction [51].

Empagliflozin gained evidence for HFpEF and HFmrEF attributable to the results of the EMPEROR-Preserved trial (which included patients with an ejection fraction above 40%). Empagliflozin 10 mg once daily reduced a composite end-point of worsening heart failure or cardiovascular death (hazard ratio, 0.79; 95% confidence interval [CI], 0.69 to 0.90; P<0.001), a result driven by a significant reduction in the risk of worsening heart failure (with no difference in death from cardiovascular causes) [52]. Likewise, in the DELIVER trial (heart failure patients with an ejection fraction above 40%), dapagliflozin 10 mg od reduced the events of a similar primary composite end-point (hazard ratio, 0.82; 95% confidence interval [CI], 0.73 to 0.92; P<0.001). Once again, this effect is attributable to the reduction of the worsening heart failure events, without significant effects on cardiovascular mortality [53]. As a result, clinical guidelines have been harmonized and currently recommend empagliflozin and dapagliflozin (unique dose of 10 mg per day) in HFpEF and HFmrEF for the reduction of the risk of HF hospitalization or cardiovascular death (class I recommendation in European guidelines, class IIa recommendation in American guidelines) [50,54].

Important evidence for using SGLT2i in heart failure derives from the EMPULSE trial, in which empagliflozin was initiated in hospitalized acute heart failure after stabilization, regardless of ejection fraction or diabetes status. The primary analysis was a win ratio, being a composite of death, heart failure events, time to first heart failure event, and modifications in KCCQ. Empagliflozin proved a better win ratio, with a statistically significant result (win ratio 1.36, 95% CI 1.09-1.68, p=0.0054), with consistent results across the prespecified subgroups [55]. Besides this combination of prognostic and symptomatic benefits, empagliflozin also proved significant results on various indices of decongestion, suggesting that early initiation of empagliflozin in hospitalized acute heart failure patients also has the potential to contribute to an early and sustained decongestion [56].

Regarding the benefits of SGLT2 inhibitors in another acute setting—this time early after myocardial infarction—a recently published meta-analysis concluded that early administration of SGLT2i post-myocardial infarction may be beneficial by reducing the risk of recurrent major adverse cardiovascular events (MACE) or hospitalization for heart failure. However, this meta-analysis did not demonstrate a significant reduction in mortality among these patients [57].

Similar to GLP-1RA, SGLT2i is also an effective medication in chronic kidney disease. Based on findings from early studies on cardiovascular safety, specific trials have been designed to directly assess the potential beneficial effects of SGLT2i in CKD. 4 trials, CREDENCE (for canagliflozin), DAPA-CKD (for dapagliflozin), SCORED (for sotagliflozin), and EMPA-KIDNEY (for empagliflozin) proved that SGLT2i slow the progression of CKD. Whereas for canagliflozin and sotagliflozin, the effects were proven only in T2DM populations, in contrast, for empagliflozin and dapagliflozin, the effects were irrespective of the diabetic status, similar to HF trials. It is important to mention that the recommendation is to initiate dapagliflozin at an eGFR of at least 25 ml/min/1.73m^2 and empagliflozin at an eGFR of at least 20 ml/min/1.73m^2, but the administration may continue even if the renal function further deteriorates (this indication derives from the design of the studies and the characteristics of the included patients) [58].

Table 2: Major CVOTs of SGLT2i [42]

	Type 2 diabetes mellitus	**Heart failure**	**Chronic kidney disease**
Proved effects	In high-risk cardiovascular patients, it reduces the risk of major adverse cardiac events or cardiovascular death. (Besides improved glycemic control and weight loss)	Reduce the risk of heart failure-related death or hospitalization (across the entire ejection fraction spectrum) Improves decongestion in stabilized acute heart failure (empagliflozin)	Mitigate the progressive reduction of eGFR and lower the risk of renal or cardiovascular-related death
Drugs approved	Canagliflozin, Dapagliflozin, Empagliflozin, Ertugliflozin	Dapagliflozin, empagliflozin	Canagliflozin, Dapagliflozin, Empagliflozin
Guideline recommendations	Recommended as first-line add-on therapy to metformin, especially in cardiovascular high-risk, heart failure, or CKD patients	Class I recommendation in HFrEF Class I recommendation in ESC guidelines, class IIa recommendation in ACC/AHA guidelines for HFpEF	T2DM and CKD with eGFR>20 ml/min/1.73m^2 ACR>200 mg/g (and eGFR>20 ml/min/1.73m^2) ACR<200 mg/g with eGFR 20-45 ml/min/1.73m^2 CKD + heart failure

MINERALOCORTICOID RECEPTOR ANTAGONISTS (MRAs)

It is known that overactivation of the renin-angiotensin-aldosterone system and aldosterone receptors (mineralocorticoid receptors, MR) in particular, has effects beyond salt and water retention and hypertension. MR overactivation is capable of inducing inflammation and fibrosis in various organs, being involved in CKD and CV disease progression, situations in which RAAS is overly activated and aldosterone is in excess [73]. As far as metabolic derangement is involved, diabetes mellitus also induces a state of overactivation of MRs, and in obese patients there was observed a significant aldosterone production from adipose tissue was observed [74,75].

The deleterious effects of excess aldosterone are facilitated by the widespread expression of mineralocorticoid receptors throughout the body, as they are present not only in the kidneys but also in the heart, blood vessels, gastrointestinal tract, adipose tissue, and central nervous system [73].

The first therapeutic options to block MRs were the steroidal agents spironolactone and eplerenone, respectively.

The first results for these agents came from RCTs, which tested them in HFrEF, a common entity in advanced stages of cardio-renal-metabolic syndrome. In RALES trial, conducted in 1999, spironolactone reduced all-cause mortality by 30% (RR, 0.70; 95% CI, 0.60 to 0.82; P<0.001) and the risk of heart failure hospitalization by 35% (RR 0.65; 95% CI, 0.54 to 0.77; P<0.001), besides observed benefits on improvement regarding the symptoms of heart failure [76]. Eplerenone gained evidence from the EMPHASIS-HF trial, which proved a significant reduction of the primary composite endpoint of CV death or heart failure hospitalization (HR, 0.63; 95% CI, 0.54 to 0.74; P<0.001) [77]. Further trials provided evidence for steroidal MRAs, namely eplerenone, early after myocardial infarction. EPHESUS and REMINDER trials found that eplerenone, early initiated after MI, in patients with clinical signs and symptoms of heart failure and an ejection fraction of less than 40% could reduce all-cause mortality, length of hospitalization due to heart failure, ventricular arrhythmias, or the risk for deterioration of ejection fraction [78,79]. The beneficial effects of MR blockade in HFrEF and after myocardial infarction emphasize the important effects of aldosterone in cardiac adverse remodelling.

Regarding the HFmrEF and HFpEF, the available results are not as solid as in HFrEF. In the TOPCAT trial, 3,445 patients with symptomatic heart failure and a left ventricular ejection fraction of ≥45% were randomized to receive either spironolactone or placebo. Although the study narrowly failed to meet its primary composite endpoint (including cardiovascular death, aborted cardiac arrest, and hospitalization for heart failure), its results generated considerable debate [80]. The difference between a significant HR in American cohort (HR, 0.82; 95% CI, 0.69-0.98; p = 0.026) and a non-significant HR in Russian and Georgian cohort (HR, 1.10; 95% CI, 0.79-1.51; interaction p = 0.12) has led to speculation that the apparent neutral results of the TOPCAT trial may be due to issues with enrollment and drug adherence in the Eastern European cohort [81]. Based on the significant results on American cohort, there is a 2b recommendation in ACC/AHA guidelines on heart failure for steroidal MRA use in HFpEF and HFmrEF [50].

Hypertension in general and resistant hypertension in particular are common entities in chronic kidney patients or in obese, insulin-intolerant, or diabetic patients. Resistant hypertension is associated with a poor prognosis, causing target organ damage. The PATHWAY-2 RCT established spironolactone as a first-line agent in resistant hypertension, on top of maximum tolerated doses of ACEI/ARB, calcium-channel blocker, and thiazide diuretic [82].

The main limitation of steroidal MRAs' use is the risk of hyperkalemia, a risk observed since the early trials and considered relatively significant, particularly in a population with chronic kidney disease. A meta-analysis that included the landmark RCTs of steroidal MRAs proved that the risk of hyperkalemia and the benefits are inversely proportional to the eGFR (with unclear benefits compared to high risk of hyperkalemia in patients with an eGFR<30 ml/min/1.73m^2) [83].

Gynecomastia and breast pain are other well-known and relatively frequent adverse effects of spironolactone (with a 10% to 1% ratio observed in the RALES trial) [73].

There is a limitation in the steroidal MRAs' potential for broader cardiorenal protection, given the fact that their widespread use is limited by hormonal adverse effects or, in advanced CKD, by a significant risk of hyperkalemia. Moreover, data regarding the direct effects of steroidal MRAs on slowing CKD are unconvincing. There is a meta-analysis that proposes some benefits on intermediate endpoints such as albuminuria or eGFR slope, albeit at the cost of significant risk of hyperkalemia, worsening renal function, or gynecomastia [84].

The novel class of non-steroidal mineralocorticoid receptor antagonists (nsMRAs) has emerged in an effort to overcome these limitations while preserving the beneficial effects of the steroidal MRAs.

Finerenone is the most prominent agent of this pharmacological class, with several advantages over its steroidal counterparts: a comparable potency of MR inhibition but with a much higher selectivity, virtually no sexual side-effects, a more balanced tissue distribution between kidneys and the heart (in comparison with sMRA which are more concentrated at the renal level) and a shorter plasma half-time, which might contribute to a lower risk of hyperkalemia [85,86].

The first RCTs investigating finerenone were FIDELIO-DKD and FIGARO-DKD. FIDELIO-DKD primarily enrolled diabetic patients suffering from advanced CKD with prominent albuminuria, and there was a prespecified primary composite kidney endpoint. FIGARO-DKD enrolled diabetic patients with moderate albuminuria associated with a wider spectrum of CKD and stated a primary composite cardiovascular endpoint [85]. The results from these 2 RCTs and from their pooled analysis (FIDELITY) form the basis for the KDIGO guideline recommendation of finerenone in CKD: in patients with diabetic nephropathy, with an eGFR>25 ml/min/1.73 m^2 and with an albuminuria >30 mg/g, despite a maximum dose of ACEI/ARB [72]. Apart from reducing the kidney disease progression, finerenone reduced cardiovascular risk (HR 0.86, 95% CI: 0.78-0.95) and the risk of heart failure hospitalization (HR 0.78, 95% CI 0.66-0.92) in diabetic CKD patients [86].

The latter FINEARTS-HF trial provides the first quality results for MRAs (particularly nsMRA, finerenone) in HF with EF above 40%. In this RCT, finerenone reduced the risk of a primary composite endpoint formed by worsening heart failure events and cardiovascular death with 16% (rate ratio, 0.84; 95% confidence interval [CI], 0.74 to 0.95; P=0.007), driven by a significant reduction in worsening heart failure events, similar to SGLT2i results in the same patient population [87]. Compared to the previous ones, FINEHEARTS was a revolutionary trial also by the population included, with approximately 60% not having CKD or diabetes, suggesting that there may be important direct effects on the heart [88].

The recent FINE-HEART meta-analysis allows for the formulation of global conclusions regarding finerenone as far as cardiovascular and renal outcomes are concerned. This meta-analysis included the three RCTs, FIDELIO-DKD, FIGARO-DKD, and FINEARTS-HF, encompassing a total of 18991 patients. 12.1% of the included patients concurrently had HF, CKD, and diabetes, the main conditions encompassed in the CKM syndrome. The results indicate that finerenone reduces the risk of heart failure hospitalization (HR: 0.83; 95% CI: 0.75-0.92; $P < 0.001$) and of a composite kidney outcome, thus delaying CKD progression (HR: 0.80; 95% CI: 0.72-0.90; $P < 0.001$). Although not succeeding in proving risk reductions in cardiovascular death (HR 0.89; 95% CI: 0.78-1.01; P = 0.076), finerenone seems to reduce the risk of all-cause death (HR: 0.91; 95% CI: 0.84-0.99; P = 0.027) [88].

Currently, the sole recommendation for finerenone within cardiology guidelines is the class IA recommendation in the 2023 ESC Guidelines for the management of cardiovascular disease in patients with diabetes, in patients with type 2 DM and CKD (UACR>300 mg/g or eGFR 25-60 ml/min/1.73m^2 and UACR>30 mg/g), in addition to ACE-I or ARB, to reduce the risk of cardiovascular events or kidney failure [26].

This recommendation, similar to those related to SGLT2i or GLP-1RA, empowers all medical doctors involved in the management of CKM syndrome to take proactive measures aimed at improving the prognosis of these patients. It remains to be seen what future heart failure guidelines will unveil regarding nsMRA indications, probably related to future trials that may investigate the effects of finerenone in this population.

CONCLUSION

Management of cardiovascular disease within the cardiorenal metabolic (CKM) syndrome requires a comprehensive, individualized approach, guided by cardiovascular risk stratification. While lifestyle interventions remain foundational, pharmacologic therapy plays a pivotal role in improving prognosis and quality of life.

Standard treatments such as RAAS blockade—with ACE inhibitors, ARBs, and steroidal MRAs—form the therapeutic backbone. However, recent advances support the early initiation of novel agents with proven benefits across all three CKM components.

GLP-1 receptor agonists and dual GLP-1/GIP agonists (e.g., tirzepatide) not only promote glycemic control and weight reduction but also lower the risk of major adverse cardiovascular events and may preserve renal function. SGLT2 inhibitors have demonstrated robust prognostic benefits in heart failure—regardless of ejection fraction—and chronic kidney disease, independent of glycemic status. Finerenone, a non-steroidal mineralocorticoid receptor antagonist, is recommended in diabetic kidney disease with albuminuria and shows emerging evidence of efficacy in HFpEF and HFmrEF, although formal guideline recommendations are still pending.

Optimizing therapeutic strategies with both established and novel agents is essential for altering the course of heart disease in CKM syndrome and addressing its complex, multisystem pathophysiology.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Authors' contribution

Conceptualization, A.G.F., S.H. and S.M.S., methodology, M.J..; formal analysis, M.F.; data curation, E.R.; writing—original draft preparation, A.G.F., S.A.P.; writing—review and editing, E.C., R.D.G., M.F., E.R.; visualization, R.D.G.; supervision, S.M.S.; project administration, S.H. All authors have read and agreed to the published version of the manuscript.

Abstract: Background and Aim: Digital skills of healthcare professionals are recognized as critical for the successful digital transformation of healthcare. The present study aims to examine the relationship between the digital skills of healthcare professionals and the organizational structures of hospitals. Methods: In this cross-sectional study, using the convenience sampling method, 857 healthcare professionals, working in Greek military and civilian hospitals, voluntarily participated. Data were collected between July and November 2021 through a structured questionnaire, based on the Digital Competence framework. Digital skills were categorized into five subscales: information, communication, content creation, problem solving, and safety skills. Statistical analysis was performed with SPSS 26.0, with p-values <0.05 considered statistically significant. Results: Cronbach's alpha values for all subscales were (α)>0.8, indicating high reliability. Younger participants showed higher scores (p<0.001). The mean scores for information, communication, content creation, problem solving and safety skills in military hospitals were calculated as 52.1 (SD=32.3), 50.6 (SD=31.8), 48.4 (SD=33.3), 49.8 (SD =30.8) and 52.8 (SD=34.1) respectively, while in civilian hospitals they were calculated as 45.1 (SD=32.2), 44.5 (SD=29.5), 41.8 (SD=32.4), 41.5 (SD=30.8) and 47.1 (SD=34.5) respectively. Conclusions: Healthcare professionals in military hospitals exhibit higher digital competence compared to their counterparts in civilian hospitals. Identifying the organizational factors that promote greater digital competence among healthcare professionals provides essential information to policymakers and healthcare managers for implementing targeted organizational improvements.

Keywords: Digital skills, Healthcare professionals, Military hospitals, Digital Competence framework

INTRODUCTION

The management of competencies and skills in the healthcare sector has drawn significant attention from international organizations, recognizing that a well-trained workforce is essential for ensuring patient safety and delivering high-quality care [1,2]. In alignment with the continuous advancements in medical technology, the necessity for healthcare professionals to develop new skills has become increasingly urgent [3,4]. This need was starkly highlighted during the recent COVID-19 pandemic, where the heightened digital demands of healthcare services underscored the importance of sufficient digital capabilities [5,6].

In particular, digital skills are deemed critical not only for the effective management of healthcare organizations but also for medical diagnosis, treatment monitoring, patient care, and decision-making processes [7,8]. Within the healthcare domain, digital competence encompasses knowledge of digital literacy and technology as essential tools for the patient-centered provision of quality healthcare services. It reflects the dynamic interaction between healthcare professionals, patients, and colleagues, as well as the drive to acquire professional expertise in digital technology [9,10].

It is widely recognized that digital competencies are essential for the effective integration of health technologies into routine clinical practice. Numerous processes are now carried out digitally, such as patient monitoring, where electronic health records and vital sign monitoring systems enable doctors and nurses to track patient status in real time. Material procurement is also facilitated through electronic systems, enhancing both accuracy and efficiency. Furthermore, telemedicine plays a pivotal role, particularly in military hospitals, by enabling the delivery of healthcare services to remote areas and military bases. Digital tools further support decision-making by allowing healthcare professionals to analyze data and make evidence-based decisions more efficiently [3,11,12].

In Greece, military hospitals offer more structured training programs for digital skills, supported by military frameworks that emphasize continuous professional development of their personnel. These programs encompass modules on the management of digital tools, telemedicine, and electronic patient record systems, reflecting the military's long-standing tradition of structured training and lifelong education. Additionally, military healthcare professionals are often encouraged to engage in e-learning programs to further enhance their expertise in healthcare technologies.

Conversely, in public hospitals, training programs for digital skills vary depending on the institution and the extent of technological integration. Significant advancements have been observed in large hospitals that have adopted electronic medical records; however, training opportunities remain limited due to resource constraints and time pressures. Healthcare professionals, including nurses and doctors, typically receive training through Ministry of Health initiatives or European-funded programs such as eHealth and Horizon 2020 [9,10].

Despite extensive research on digital skills, a literature review from the past decade indicates a scarcity of studies that examine the digital competencies of healthcare professionals within a specific and well-defined conceptual framework. One such framework is the European Digital Competence (DigComp) Framework, created by the European Union as a common umbrella of digital competences for its citizens, which defines digital competence domains, indicators for each domain, competence levels, examples of knowledge, skills, and attitudes, as well as examples of application [13]. Moreover, limited research has explored the associations between digital skills and the organizational work environment. To the best of our knowledge, no prior studies have investigated differences in this domain between military and civilian healthcare professionals.

Therefore, the objective of this paper is to address this research gap by examining the relationship between digital skills of healthcare professionals and the organizational structures of their work environments. We aim to contribute evidence on the organizational factors influencing healthcare professionals' digital competencies, which can inform policymakers and healthcare managers' efforts to implement targeted organizational improvements.

MATERIALS AND METHODS

Study Design

A cross-sectional survey utilizing a descriptive study design was conducted based on prior research, which demonstrated that the Digital Competence Indicator tool is a reliable and valid measurement scale applicable to Greek doctors and nurses [14]. The study addressed two primary research questions: (1) How are healthcare professionals' digital skills assessed? and (2) Are there differences in the digital skills of healthcare professionals between military and civilian hospitals?

The present study was conducted as part of the research activities of the Department of Nursing at the Hellenic Mediterranean University and received ethical approval from the Review Committee (Protocol No.: 4634/29-03-2021). Additionally, the necessary permissions were obtained from the Scientific Committees of all participating hospitals (Protocol No.: 5584/1973/26-06-2021). Data were collected using a self-assessment questionnaire, with the principal investigator maintaining sole access to the collected data. Participation was entirely voluntary, and all participants were informed both verbally and via an information/consent form that completing and returning the questionnaire constituted their consent to participate in the study. The information/consent form was approved by the above Scientific Committees. The research adhered strictly to the European Union's General Data Protection Regulation, ensuring full compliance with personal data protection standards.

Participants and settings

A convenience sample of doctors and registered nurses was selected from seven tertiary care hospitals in Greece. This particular sampling method was preferred because it offers time and cost savings, ease of access, and an abundance of qualitative data. However, it carries the risk of bias and systematic errors, and therefore, research findings cannot be accurately generalized beyond the study sample. The selection of hospitals was based on the diversity of organizational structures between military and civilian institutions, as well as the aim of achieving a large sample size. The study population size was calculated using a 95% confidence interval and a 5% margin of error, ensuring that the final sample accurately represented healthcare professionals in Greek hospitals. The target sample size was N>800. A total of 1207 questionnaires were distributed, and 876 were collected, of which 19 were invalid due to incomplete responses. Thus, the study population is N=857.

The inclusion criteria for participation were employment in either a military or civilian hospital, professional status as a doctor or nurse, and, for nurses, registration as per the European Qualifications Framework (EQF). The distribution of questionnaires was proportional to the size of each hospital, based on the number of medical and nursing staff within the institutions. Data collection occurred during staff meetings, where participants from various work positions within the hospitals were approached, provided with explanations of the study objectives, and given clarifications on completing the questionnaire. Data collection was conducted between July and November 2021.

Research tool

Data were collected using a validated 37-item paper-based questionnaire. It is built on the European DigComp Framework, which comprehensively defines the elements of digital competence as a combination of skills, abilities and attitudes essential for incorporating data processing into the professional careers of healthcare providers [13,15].

The questionnaire consisted of two parts. The first part captured demographic characteristics, including gender, age, educational level, profession, specialty, hospital type, professional experience, administrative responsibilities, and possession of digital skills certification. The second part assessed 26 digital skills, organized into five competency domains (subscales): information, communication, content creation, problem-solving, and safety skills (Table 1).

Table 1: Competence area and digital skills of the questionnaire. Adapted from the European Commission's DigComp framework [13]

Competence Area	Digital Skills
Information Skills	1. Finding information about goods and services
	2. Obtaining information from public authority websites
	3. Reading or downloading online news/newspapers/news magazines
	4. Copying or moving a file or folder
	5. Seeking health-related information
Communication Skills	6. Sending/receiving emails
	7. Telephoning over the internet/video calls (via webcam) over the internet
	8. Participating in social networks
	9. Posting messages to chat sites
	10. Uploading self-created content to any website to be shared
Content Creation Skills	11. Creating websites or blogs
	12. Writing a computer programme using a specialized programming language
	13. Using copy and paste tools to duplicate or move information within a document
	14. Creating electronic presentations with presentation software (e.g., slides), including e.g., images, sound, video, or charts
	15. Using basic arithmetic formulae to add, subtract, multiply, or divide figures in a spreadsheet
Problem-Solving Skills	16. Connecting and installing new devices
	17. Installing a new or replacing an old operating system
	18. Modifying or verifying the configuration parameters of software applications
	19. Doing an online course
	20. Buying or ordering goods or services for private use (last 12 months) over the internet
	21. Selling online
	22. Job search or sending an application
	23. Internet banking
	24. Making an appointment with a practitioner via a website
Safety Skills	25. Using any kind of IT security software or tool (anti-virus, anti-spam, firewall, etc.) in order to protect private computers and data
	26. Updating one or more security products at least occasionally

Subscale values were calculated on a scale ranging from 0 to 100, with scores approaching 0 reflecting a more negative evaluation of the variable and scores approaching 100 reflecting a more positive assessment.

The questionnaire provided a concise yet compelling assessment of the Information Technology (IT) skills of hospital doctors and nurses. Designed for ease of use and brevity, it was particularly suitable for hospital settings often characterized by high workloads and limited time for activities outside core medical and nursing responsibilities. Participants rated the extent of their computer usage for each activity on a five-point Likert scale, ranging from 1 ("not at all") to 5 ("very much").

Data Analysis

Statistical analysis was performed using SPSS (Statistical Package for Social Sciences) version 26.0. Continuous variables were expressed as mean ± standard deviation (SD) and categorical variables were presented as absolute numbers (n) and percentages (n%). The normality of variables was assessed using the Shapiro-Wilks test, alongside graphical methods such as the Normal Q-Q plot, Detrended Normal Q-Q plot, and Box Plot. For all statistical tests, differences were considered significant at $p < 0.05$. Effect sizes weren't reported. The independent t-test was employed to compare the means of two groups, while one-way analysis of variance (ANOVA) was used for comparisons involving more than two group means.

RESULTS

Participant's characteristics

The study population comprised 857 Greek healthcare professionals employed across seven tertiary care hospitals. The results indicate that 538 participants (62.8%) were female, while 319 (37.2%) were male, with a mean age of 39.7 years (SD = 10.0). Of the total, 657 participants worked in military hospitals, while 200 worked in civilian hospitals. Indicatively, it is reported that the number of military doctors and nurses in hospitals, at the present time, amounts to approximately 1,700 people.

Specifically, among the military hospitals, 384 participants were from the 251 Hellenic Air Force General Hospital, 110 from the 401 General Military Hospital of Athens, 66 from the Athens Naval Hospital, and 97 from the General Military Training Hospital. Among civilian hospitals, 82 participants were from the Sismanoglio General Hospital of Attika, 51 from the Asklepieio Voulas General Hospital, and 67 from the Henry Dunant Hospital Center.

The majority of participants were registered nurses (70.2%), with doctors comprising 29.8% of the sample. Considering the nature of the study population, where nurses outnumber doctors by more than twice, the preponderance of the female gender can be explained by the fact that the nursing profession in Greece has traditionally been considered female-dominated for many years. The average professional experience was estimated at 15.3 years. Regarding educational levels, 528 participants (61.6%) held a Bachelor of Science (BSc) degree, 275 (32.1%) had also completed a Master's degree, and 54 (6.3%) held a PhD degree. Examining the level of education by profession, doctors have a higher proportion of PhD holders (5.4%) than nurses (0.9%). Conversely, nurses have a higher percentage of master's degree holders (22.8%) than doctors (9.3%). The demographic characteristics of the study population are summarized in Table 2.

Table 2: Demographic characteristics of participants (N = 857).

		Hospital				**Total**		
		Civilian hospital		***Military hospital***				
		N	N %	N	N %	N	N %	p-value
Age (years)*		40.6 (9.9)		39.4 (10)		39.7 (10)		0.143
Gender	Female	134	67.0%	404	61.5%	538	62.8%	0.158
	Male	66	33.0%	253	38.5%	319	37.2%	
Educational level	BSc	136	68.0%	392	59.7%	528	61.6%	0.092
	MSc	52	26.0%	223	33.9%	275	32.1%	
	PhD	12	6.0%	42	6.4%	54	6.3%	
Profession	Medical Doctor	53	26.5%	202	30.7%	255	29.8%	0.250
	Registered Nurse	147	73.5%	455	69.3%	602	70.2%	

**Note. Age expressed as mean (standard deviation)*

Digital Skills

Regarding digital skills, the results are overall. The mean scores of all digital skills subscales indicate an average level and are as follows: information skills, 52.1 (SD = 32.3); communication skills, 50.6 (SD = 31.8); content creation skills, 48.4 (SD = 33.3); problem-solving skills, 49.8 (SD = 30.8); and safety skills, 52.8 (SD = 34.1). Median scores, interquartile ranges (IQR), and p-values of the above subscales are presented in Table 3.

The reliability of the subscales was confirmed, with Cronbach's alpha values indicating high internal consistency: information skills (5 items; $\alpha = 0.95$), communication skills (5 items; $\alpha = 0.95$), content creation skills (5 items; $\alpha = 0.95$), problem-solving skills (9 items; $\alpha = 0.97$) and safety skills (2 items; $\alpha = 0.92$). Cronbach's alpha was calculated by group. It is worth noting that the high Cronbach's alpha values (>0.9) observed in the study results are likely due to the narrowness of the aspect structure of the measurements' tool subscales. However, the measurement scale was taken as an existing structure from the European DigComp Framework and was not developed by the researchers. Future survey to explore the factor structure by removing some potentially redundant items or adding new ones is a challenge for the present investigators.

Table 3: Median scores, IQR, and p-values of subscales (information skills, communication skills, content creation skills, problem-solving skills, safety skills) per type of hospital

		Hospital		
		Civilian hospital	**Military hospital**	**Total**
Information skills	Median	45.00	60.00	55.00
	IQR	63.75	60.00	60.00
	p-value	<0.001		
Communication skills	Median	40.00	55.00	50.00
	IQR	50.00	65.00	60.00
	p-value	0.002		
Content creation skills	Median	40.00	50.00	50.00
	IQR	60.00	67.50	65.00
	p-value	0.001		
Problem-solving skills	Median	30.60	52.80	50.00
	IQR	58.30	52.80	55.60
	p-value	<0.001		
Safety skills	Median	37.50	62.50	62.50
	IQR	71.88	62.50	62.50
	p-value	0.007		

The mean scores across all five subscales of the measurement tool were found to differ significantly between military and civilian hospitals. Specifically, the mean score for the "Information skills" subscale in military hospitals was M = 54.2 (SD = 32.1), compared to M = 45.1 (SD = 32.2) in civilian hospitals, with t(855) = -3.522, $p < 0.001$. For the "Communication skills" subscale, the mean score in military hospitals was M = 52.4 (SD = 32.3), while in civilian hospitals it was M = 44.5 (SD = 29.5), with t(855) = -3.088, p = 0.002.

Similarly, the "Content creation skills" subscale showed a mean score of M = 50.4 (SD = 33.3) in military hospitals versus M = 41.8 (SD = 32.4) in civilian hospitals, with t(855) = -3.236, p = 0.001. For "Problem-solving skills," the mean score in military hospitals was M = 52.4 (SD = 30.4), compared to M = 41.5 (SD = 30.8) in civilian hospitals, with t(855) = -4.395, $p < 0.001$. Lastly, the "Safety skills" subscale yielded a mean score of M = 54.6 (SD = 33.8) in military hospitals and M = 47.1 (SD = 34.5) in civilian hospitals, with t(855) = -2.740, p = 0.006.

The mean values (SD) of digital skills (information, communication, content creation, problem-solving, and safety skills) by hospital type are illustrated in Figure 1.

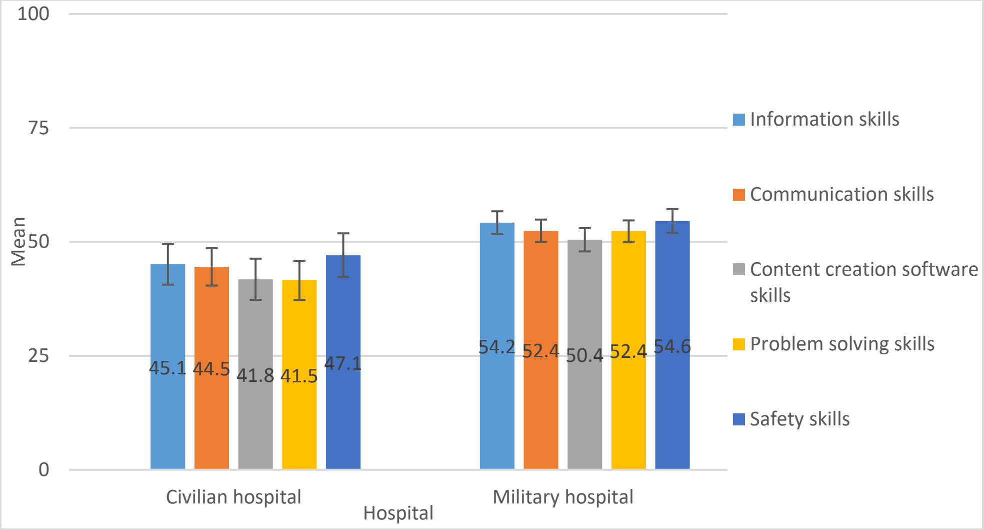
DISCUSSION

Based on the theoretical framework outlined, the findings of this study align with existing research emphasizing the growing importance of digital skills for healthcare professionals. Digital competence is essential not only for the effective delivery of healthcare services but also for ensuring patient safety and enhancing the overall efficiency of healthcare systems [16,17]. These competencies enable healthcare professionals to manage patient data effectively, navigate electronic health records [18,19], process large volumes of information[20], and utilize telemedicine tools [21,22]—capabilities that are no longer optional, but essential and fundamental to healthcare professionals' expertise [10,23,24].

In the present study, digital skills of the Greek study population can be characterized as good, as they are proven to be above the median level, with safety and information skills gathering the highest averages, communication and problem-solving skills being at the median level, and content creation skills being the weakest, with a score just below the median level. It is noteworthy that content creation skills require particular IT knowledge and technical skills, such as developing or maintaining computer systems, hardware, or software, and writing a computer program using a specialized programming language. Thus, they appear as the digital skills category with the lowest proficiency rates in the majority of occupations in Europe [25].

The above levels of digital skills are in line with a similar Greek study, where the digital competence of healthcare professionals is moderate to good [26]. Research conducted on healthcare professionals in European countries shows that the majority have medium levels of digital competence. A study carried out in Moldova found advanced levels of digital skills in the areas of information and communication and moderate levels in the areas of content creation, safety, and problem solving[6]. In Finland, the levels of digital competence are relatively high[27], while in some regions in Finland and Sweden, digital skills are reported as adequate but with several shortcomings[16] and in Catalonia, they appear at a basic and intermediate level [28]. According to the European Centre for the Development of Vocational Training (Cedefop), in terms of digital intensity measurements in the EU for 2021, the level of digital skills for health professionals appears as basic to intermediate, and only in a percentage of 13.4% as advanced [29].

Figure 1: Clustered Bar Mean (95% CI) of Information skills, Mean of Communication skills, Mean of Content creation software skills, Mean of Problem-solving skills, Mean of Safety skills by Hospital (Error Bars: 95% CI).



Consistent with prior research, this study also revealed that younger healthcare professionals demonstrated higher levels of digital competence, particularly in domains such as communication and content creation. Literature suggests that younger professionals tend to exhibit greater eHealth literacy and are more adept at using digital tools [30,31]. This generational disparity in digital skills underscores the need for targeted interventions that provide older healthcare professionals with the necessary training and support to enhance their digital proficiency. Hospital management can organize continuing education programs that are easily accessible and tailored explicitly to older professionals, such as online courses, interactive sessions, or specially designed workplace courses.

It is worth noting that, in the measurement tool, all possible demographic confounding factors were included to avoid biased conclusions. According to the literature review, the demographic factors found to be associated with digital skills levels were age, type of occupation, gender, professional experience, and educational level, which were studied in our research [30,32,33]. However, the results of this study found no significant differences in digital skills based on gender, professional experience, specialty, or educational level.

In addition, research underscores the critical role of the working environment in shaping digital literacy. For instance, De Veer and Francke (2010) observed that attitudes toward electronic health records varied significantly depending on the type of healthcare organization [11]. Similarly, Jarva et al. (2023) as well as Rippen et al. (2013), emphasized that strong organizational support—through timely interventions and the provision of adequate resources—is essential for the successful adoption of digital technologies by healthcare professionals [9,34]. Similarly, the findings of the present survey revealed significant differences in digital skills between military and civilian hospitals, with the predominance of health professionals in military hospitals.

This superiority can be attributed to several factors, including the structured nature of military institutions, where digital training and protocols are more systematically integrated into daily operations [35,36]. Military hospitals often place a stronger emphasis on technical proficiency and operational readiness [37,38], which likely fosters the development of higher digital literacy among their staff. Moreover, they prioritize digital training for their personnel as part of their operational strategies and compliance with applicable protocols. In contrast, civilian hospitals may face a broader array of challenges, including inconsistent administrative policies and slower technology adoption due to resource constraints [35,39].

In Greece, in recent years, the Ministry of Digital Governance, in coordination with the Ministry of Health and other bodies, has been working to strengthen the digital competence of doctors and nurses through the implementation of a national e-health strategy. Among the objectives are to improve the continuous education of health professionals and to ensure access to reliable digital information and tools [40]. However, training programs for civilian health professionals are usually their personal responsibility, as organizational procedures are inadequate. In contrast, in military environments, such programs are supported by the respective military education sectors, financed with their own resources and means, and organized on a regular and periodic basis for the training of all their personnel.

The operation of military hospitals, with adherence to hierarchical procedures, is a significant factor in their ability to implement and train staff in digital technologies efficiently. These institutions often adopt new systems at a faster pace, which may explain the consistently higher levels of digital proficiency observed among healthcare personnel in military settings. Such an organizational advantage aligns with the findings of Ludwick and Doucette (2009), who emphasized that organizational readiness and robust support systems are critical to the successful implementation of electronic health records [41].

Furthermore, the constant exposure to technology [36,42] and digital tools [43,44] observed in military settings provides healthcare professionals with more opportunities to enhance their digital skills. In contrast, civilian hospitals face a variety of challenges that may hinder the development of such competencies. In Greece, these challenges include diverse administrative structures, slower decision-making processes, and limited access to resources for digital training [45,46]. The inherent flexibility within civilian hospital operations may further contribute to inconsistencies in the application and development of digital skills among healthcare professionals. This discrepancy could reflect differences in organizational priorities and the availability of technological resources within these institutions.

A noteworthy area where military healthcare professionals excel is in safety skills, likely due to the stringent data protection and cybersecurity protocols mandated within military environments [47,48]. This focus on safeguarding sensitive patient and operational data, cultivates a more advanced understanding of cybersecurity measures among military hospital staff. Although civilian hospitals also prioritize data security, they often encounter greater challenges in implementing uniform protocols due to variations in organizational structure and resource constraints.

Another significant disparity lies in problem-solving skills. Military healthcare professionals appear to be better equipped to handle technical challenges, potentially due to the emphasis on problem-solving as an integral part of military training and operational effectiveness [49]. In contrast, the less regimented procedures commonly found in civilian hospital settings may provide healthcare professionals with fewer structured opportunities to develop and refine these skills.

We consider that the Ministry of Health or the EU frameworks could adopt military-style training modules emphasizing techniques such as extensive practical training, simulation exercises, the development of specialized centers of expertise, field training techniques, the use of existing training frameworks, needs- and context-based design, continuous harmonization with modern standards, and synergies between civilian and military professionals. One such model is the Common Security and Defence Policy (CSDP) Training Programme, an EU policy to provide senior civil and military officers with the necessary skills and knowledge in crisis management situations [50].

Future Implications

We believe that civil-military cooperation, by embracing strengths and avoiding weaknesses, could improve the overall digital capability of health professionals. As military hospitals provide a more conducive environment for developing digital skills, civilian hospitals could benefit from adopting some of the structured approaches used in military hospitals. With the continuous evolution of healthcare technology, it is essential that all healthcare professionals, irrespective of their work environment, are supported in acquiring and maintaining high levels of digital competence.

Digital skills among healthcare professionals represent a burgeoning field of research that has experienced rapid growth over the past decade. The findings of this study highlight the need to explore further the role of institutional support in fostering digital skills, as well as the factors contributing to digital competence gaps among healthcare professionals across different organizational settings. These results hold international relevance, given the global significance of digital transformation in the healthcare sector. With additional research conducted in similar settings across various countries, these findings could be generalized to further advance digital literacy and transformation in healthcare systems worldwide.

Limitations

This study is subject to three key limitations that may affect the generalizability of the findings. First, the participating nurses were all registered nurses (European Qualifications Framework - EQF 6) and not practicing nurses (EQF 5), and therefore, the measurement tool is validated and reliable only for registered nurses. Second, a self-assessment questionnaire was used as a measurement tool, which entails the risk of subjectivity due to overestimation or underestimation of the actual skills of the participants. Finally, the convenience sampling approach carries the risk of bias and systematic errors.

CONCLUSION

This study underscores the critical importance of digital skills among healthcare professionals, drawing attention to notable differences between staff in military and civilian hospitals. The findings indicate that military healthcare professionals generally demonstrate higher levels of digital competence, likely attributable to the structured and resource-rich environments characteristic of military hospitals. These organizational factors, which foster a more digitally skilled workforce, serve as a foundation for identifying and implementing necessary organizational improvements that healthcare managers can leverage.

However, it is important to note that both military and civilian healthcare professionals exhibited moderate levels of digital skills overall, signifying substantial room for improvement across both settings. Strengthening digital competence across the healthcare sector remains essential for meeting the demands of modern healthcare systems.

Conflicts of interest and sources of funding

The authors declare no conflict of interest. This research received no external funding.

Guidelines for authors

Thank you for your interest in the *Romanian Journal of Military Medicine.* Please read the complete Author Guidelines carefully before submission, including the section on copyright.

To ensure fast peer review and publication, manuscripts that do not adhere to the following instructions will be returned to the corresponding author for technical revision before undergoing peer review. Note that submission implies that the content has not been published or submitted for publication elsewhere except as a brief abstract in the proceedings of a scientific meeting or symposium. Once you have prepared your submission following the Guidelines, manuscripts should be submitted online at office@rjmm.ro.

EDITORIAL AND CONTENT CONSIDERATIONS

Aims and Scope

Romanian Journal of Military Medicine (RJMM) is the official journal of the Romanian Association of Military Physicians. The Journal publishes peer-reviewed original papers, reviews, meta-analyses, systematic reviews, and editorials concerned with clinical practice and research in the fields of medicine. Papers may cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Case reports and letters to the Editor may not be considered for publication.

Editorial Review and Acceptance

The acceptance criteria for all papers and reviews are based on the quality and originality of the research and its clinical and scientific significance to our readership. All manuscripts are peer-reviewed under the direction of an Academic Editor. The Editor-in-Chief reserves the right to refuse any material for review that does not conform to the submission guidelines detailed throughout this document, including ethical issues, completion of an Exclusive License Form, and stipulations as to length.

ETHICAL CONSIDERATIONS

Principles for Publication of Research Involving Human Subjects

Manuscripts must contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee and have therefore been performed following the ethical standards laid down in an appropriate version of the Declaration of Helsinki (as revised in Brazil 2013), available at: http://www.wma.net/en/30publications/10policies/b3/index.html. It should also state clearly in the text that all persons gave their informed consent before their inclusion in the study. Details that might disclose the identity of the subjects under the study should be omitted. Photographs need to be cropped sufficiently to prevent human subjects from being recognized (or an eye bar should be used).

Registration of Clinical Trials

We strongly recommend, as a condition of consideration for publication, registration in a public trials registry. Trials register at or before the onset of patient enrolment. This policy applies to any clinical trial. We define a clinical trial as any research project that prospectively assigns human subjects to intervention or comparison groups to study the cause-and-effect relationship between a medical intervention and a health outcome. Studies designed for other purposes, such as to study pharmacokinetics or major toxicity (e.g., phase 1 trials), are exempt.

We do not advocate one particular registry, but registration with a registry that meets the following minimum criteria:

– Accessible to the public at no charge;

– Searchable by standard, electronic (Internet-based) methods;

– Open to all prospective registrants free of charge or at minimal cost;

– Validates registered information;

– Identifies trials with a unique number; and

– Includes information on the investigator(s), research question or hypothesis, methodology, intervention and comparisons, eligibility criteria, primary and secondary outcomes measured, date of registration, anticipated or actual start date, anticipated or actual date of the last follow-up, a target number of subjects, status (anticipated, ongoing or closed) and funding source(s).

Plagiarism Detection

The journal employs a plagiarism detection system. By submitting your manuscript to this journal, you accept that your manuscript may be screened for plagiarism against previously published works.

Committee on Publication Ethics

The Journal subscribes to the principles of the Committee on Publication Ethics (COPE).

MANUSCRIPT CATEGORIES AND SPECIFICATIONS

All articles, except for Editorials, must contain an abstract of no more than 200 words. Abstracts for original articles should be formatted as detailed in the Word form. Titles must not be longer than 120 characters (including spaces). In every article, there must be three to ten pertinent keywords specific to the article yet reasonably common within the subject discipline.

Editorials

These are invited by the Editor-in-Chief or their delegated editor and should be a brief review of the subject concerned, with reference to and commentary about one or more articles published in the same issue of RJMM. Editorials are generally 1200–1500 words, may contain one table or figure, and cite up to 15 references, including the source article. This should be cited as Rom. J. Mil. Med. (year); (vol): [issue].

Review Articles

RJMM welcomes reviews of important topics across the scientific basis of medicine and advances in clinical practice. Most published reviews are in response to the editorial invitation, including thematically related “miniseries” of reviews. Authors considering submitting a review for RJMM are advised to canvas their possible review with the Editor-in-Chief or a colleague editor; this

avoids early rejection if the subject matter is not deemed a high priority for the Journal at the time of submission. Reviews are suggested to limit to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Meta-Analyses or Systematic Reviews

RJMM particularly welcomes the submission of Meta-Analyses and Systematic Reviews, which underpin evidence-based medicine. Guidelines for the preparation of meta-analyses and Systematic Reviews are similar to other reviews, and articles are subject to the usual peer review process. Meta-analyses and Systematic Reviews are suggested to be limited to 3500–5000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Original Articles (including clinical trials)

RJMM welcomes original articles concerned with clinical practice and research in the fields of medicine. Papers can cover the medical, surgical, radiological, pathological, biochemical, physiological, ethical, and/or historical subject areas. Clinical trials are afforded expedited publication if deemed suitable. RJMM also deals with the basic sciences and experimental work, particularly that with clear relevance to disease mechanisms and new therapies. Original articles are suggested to be limited to 3000 words, with an abstract of up to 200 words and up to 100 references and figures or tables.

Education and Imaging

The Editors welcome contributions to the Education and Imaging section. The purpose is to present imaging for the evaluation of unusual features of common conditions or the diagnosis of unusual cases. Contributions will be reviewed by the Executive Editors. The format of the Images pages involves two parts, each of which will occupy up to one journal page. In Part 1, a case will be described briefly, including a summary of the presentation, clinical features, and key laboratory results. One to two key images will then be presented. It is helpful to the reader if the author responds to questions that follow from the images of the case, such as 'What is your diagnosis? What are the features indicated on the CT scan? What is the differential diagnosis?' Part 2 will briefly describe the imaging features, particularly those that lead to a diagnosis or are critical for management. Differential diagnosis should be mentioned. It will be useful to include either further images or pathological details that validate the imaging diagnosis. Occasionally, the presentation of analogous cases or related images from a similar case might be appropriate.

Please include between one and three references to definitive studies and appropriate reviews of the subject. The format of the Images page involves a brief background and description of the disorder of interest, together with two figures of high quality. Colored photographs are encouraged. The submission may take the form of a case report or may illustrate particular features from more than one patient.

MANUSCRIPT PREPARATION

Style

Manuscripts should follow the style of the Vancouver agreement detailed in the International Committee of Medical Journal Editors' revised 'Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Writing and Editing for Biomedical Publication, as presented at http://www.ICMJE.org/.

Spelling

The journal uses US spelling and authors should, therefore, follow the latest edition of Merriam-Webster's Collegiate Dictionary.

Units

All measurements must be given in SI units as outlined in the latest edition of Units, Symbols, and Abbreviations: A Guide for Biological and Medical Editors and Authors (Royal Society of Medicine Press, London).

Abbreviations

Abbreviations should be used sparingly and only where they ease the reader's task by reducing the repetition of long technical terms. Initially, use the word in full, followed by the abbreviation in parentheses. Thereafter, use the abbreviation.

Trade names

Trade names should not be used. Drugs should be referred to by their generic names, rather than brand names.

Parts of the Manuscript

The manuscript should be submitted in separate files: the title page and the main text file according to the Word model.

Title page

The title page should contain (i) a short informative title that contains the major keywords. The title should not contain abbreviations; (ii) the full names of the authors (if possible, not more than 5 authors per title); (iii) the author's institutional affiliations at which the work was carried out; (iv) the full postal and email address, plus telephone number, of the author to whom correspondence about the manuscript should be sent; (v) disclosure statement; and (vi) acknowledgments. The present address of any author, if different from that where the work was carried out, should be supplied in a footnote.

Disclosure statement

The source of financial grants and other funding should be acknowledged, including a frank declaration of the authors' industrial links and affiliations. In the case of clinical trials or an article describing the use of a commercial device, therapeutic substance, or food must state whether there are any potential conflicts of interest for each of the authors: failure to make such a statement may jeopardize the article being sent out for peer review.

Acknowledgments

The contribution of colleagues or institutions should also be acknowledged. Thanks to anonymous reviewers are not allowed.

Main text

As papers are double-blind peer-reviewed, the main text file should not include any information that might identify the authors. The main text of the manuscript should be presented according to the word model. Figures and supporting information should be submitted as separate files. Footnotes to the text are not allowed, and any such material should be incorporated into the text as parenthetical matter.

Abstract and keywords

Original articles must have a structured abstract that states in 200 words or fewer the purpose, basic procedures, main findings, and principal conclusions of the study. If appropriate, divide the abstract with the headings: Background and Aim, Methods, Results, and Conclusions. The abstracts of reviews need not be structured. The abstract should not contain abbreviations or references. Three to ten keywords should be supplied below the abstract and should be taken from those recommended by the US National Library of Medicine's Medical Subject Headings (MeSH) browser – http://www.nlm.nih.gov/mesh/meshhhome.html.

Text

Authors should use the word form in editing the submitted material.

References

The Vancouver system of referencing should be used. In the text, references should be cited using Arabic numerals in square parentheses in the order in which they appear. If cited only in tables or figure legends, number them according to the first identification of the table or figure in the text. In the reference list, the references should be numbered and listed in order of appearance in the text. Cite the names of all authors when there are six or fewer; when seven or more, list the first three followed by et al. Names of journals should be abbreviated in the style used in MEDLINE. References to unpublished data and personal communications should appear in the text only.

Use Index Medicus as the style guide for references and other journal abbreviations.

Tables

Tables should be self-contained and complement, but not duplicate, the information contained in the text. Number tables consecutively in the text in Arabic numerals. Type tables on a separate page with the legend above. Legends should be concise but comprehensive – the table and legend must be

understandable without reference to the text. Column headings should be brief, with units of measurement in parentheses; all abbreviations must be defined in footnotes. Footnote symbols: †, ‡, •, ‣ should be used (in that order) and *, **, *** should be reserved for P-values. Statistical measures such as SD or SEM should be identified in the headings.

Figure legends

Type figure legends on a separate page. Legends should be concise but comprehensive – the figure and its legend must be understandable without reference to the text. Include definitions of any symbols used and define/explain all abbreviations and units of measurement. Indicate the stains used in histopathology. Identify statistical measures of variation, such as standard deviation and standard error of the mean.

Figures

All illustrations (line drawings and photographs) are classified as figures. Figures should be numbered using Arabic numerals and cited in consecutive order in the text. Each figure should be supplied as a separate file, with the figure number incorporated in the file name.

Preparation of Electronic Figures for Publication:

Although low-quality images are adequate for review purposes, publication requires high-quality images to prevent the final product from being blurred or fuzzy.

SUBMISSION REQUIREMENTS

Manuscripts should be submitted online at office@rjmm.ro. A cover letter containing an authorship statement should be included. The cover letter should include a statement covering each of the following areas:

– Confirmation that all authors have contributed to and agreed on the content of the manuscript, and the respective roles of each author. It is not accepted that the idea of equal contribution.

– Confirmation that the manuscript has not been published previously, in any language, in whole or in part, and is not currently under consideration elsewhere.

– A statement outlining how ethical clearance has been obtained for the research, particularly concerning studies involving human subjects and animal experimentation. The institutional ethics committees approving this research must comply with acceptable international standards (such as the Declaration of Helsinki), and this must be stated.

– For research involving pharmacological agents, devices, or medical technology, a clear Conflict of Interest statement about any funding from or pecuniary interests in companies that could be perceived as a potential conflict of interest in the outcome of the research.

– For clinical trials, these have been registered in a publicly accessible database (see more under 'ETHICAL CONSIDERATIONS (Further Information)' later in these guidelines).

If the above items are not included in the cover letter, manuscripts cannot be sent for review. Please also note that the cover letter does not require a detailed or lengthy description of the content or structure of the manuscript itself.

Two Word files need to be included upon submission: A title page file and the main text file that includes all parts of the text in the sequence indicated in the section 'Parts of the manuscript', including tables and figure legends but excluding figures, which should be supplied separately.

The main text file should be prepared using the Word model that is to be found on the web page (http://revistamedicinamilitara.ro/wpcontent/uploads/2022/07/Macheta-articole.docx).

Each figure should be supplied as a separate file, with the figure number incorporated in the file name. For submission, high-resolution figures (at least 300 d.p.i.) saved as .eps, .jpg, or .tif files are required.

PUBLICATION PROCESS AFTER ACCEPTANCE

Accepted Articles

Accepted Articles are published online after final acceptance, and appear in PDF format only.

Proofs

Once the paper has been typeset, the corresponding author will receive an email alert containing the proof of acceptance. It is therefore essential that a working e-mail address is provided for the corresponding author.

COPYRIGHT, LICENSING, AND ONLINE OPEN

Details are on the Copyright Agreement Form that must be completed and signed when the Article is submitted.

ORIGINAL ARTICLE

A brief overview of the Epstein Barr virus and its association with Burkitt's lymphoma

Mahdieh Farzanehpour[1], **Amir M.M. Fard**[1], **Hadi E.G. Ghaleh**[1]

Abstract: *Epstein Barr virus (EBV) is known as an oncovirus and associates with several human malignancies such as Burkitt's lymphoma, other non-Hodgkin lymphomas, nasopharyngeal carcinoma, Hodgkin's disease, gastric adenocarcinoma, etc. in Burkitt's lymphoma, and the key event is the translocation of MYC gene, that increase of cell survival and aberrant expression of MYC gene. The biology of EBV and its function in the development of Burkitt's lymphoma are discussed in this review.*

Keywords: *Epstein Barr virus, oncovirus, Burkitt's lymphoma, MYC gene*

INTRODUCTION

Epstein–Barr virus (EBV), discovered in 1964 by Epstein, Achong, and Barr from cultured cells of Burkitt's lymphoma by electron microscopy [1]. The EBV is recognized as the first human tumor virus. It is associated with lymphomas, epithelial cell cancers, nasopharyngeal carcinoma, and gastric cancer [2, 3]. EBV infection is mainly transmitted by saliva. The prevalence of EBV in the worldwide population is more than 90%. Most of the EBV carrier individuals do not have any symptoms. However, it is estimated that EBV has a role in the development of approximately 200,000 new cancer cases worldwide each year. Also, it is responsible for almost 2% of all human cancers, and according to current evidence, EBV may be a co-factor in the development of other malignancies, such as breast and cervical cancer [4].

EBV virion structure

EBV (also knowns as human gammaherpesvirus 4) is a member of the Herpesviridae family and a common virus among humans. EBV has a linear, double-stranded DNA genome with a length of 184 kb in a nucleocapsid with 162 capsomeres, which is encapsulated in an envelope with external glycoprotein spikes. The virion diameter is roughly 120-180 nm [5, 6].

Replication cycle

EBV infection targets epithelial and B-cells. Eight glycoproteins are involved in virus entry depends on the type of cell (Table 1) [7]. One of the most abundant glycoproteins of EBV called GP350\220 is responsible for the binding to B-cells, in which it binds to complement receptor type 2 (CR2) on B-cells with high affinity [8]. Although this is a key step for virus attachment to the target cells, other factors also are required for infecting target cells. Major histocompatibility complex class II (MHC-II) on B-cell surface act as a co-factor that interacts with the three viral glycoprotein gp42, gL, and gH to bind the virus to B-cell [9-11].

The fusion of the viral envelope with the cell membrane begins with the interplay of gp42 and HLA class II that eventually leads to endocytosis of the virus into the cell [11]. Complement receptor 1 (also known as CD35) (CR1) is an additional adhesion factor that binds to gp350\220 and can provide a pathway for EBV entry into CD21 negative cells such as immature B-cell. Furthermore, CD35 is sufficient for EBV binding, MHC-II expression is also needed for cell entry and infection. The gp350 mediates the attachment of EBV to epithelial cells, however, it can be fulfilled by gHgL complex on CR2 negative cells [20]. The gHgL complex binds specifically to epithelial cells, not B-cells, and the gH-null virus loses the ability to link to a CR2-negative epithelial cell but still can use gp350 to bind to CR2-positive cells [21-23]. The ability of gHgL to bind to CR2 negative epithelial cells can be blocked by the presence of gp42 [21]. It also prevents the virus's ability to infect CR2-positive cells [24]. In epithelial

cells lacking CD21, the BMRF-2 protein of the virus interacts with cellular β1 integrin, and gHgL proteins interact with αvβ6\8 integrin to initiate virus fusion [25]. Endocytosis of the EBV into the vesicle and fusion of the virus with the vesicle membrane results in the release of the nucleocapsid into the cytoplasm. As the nucleocapsid dissolves, the genome is transferred to the nucleus [26].

Table 1: Roles of envelope glycoproteins in entry to epithelial and B-cells

Gene	Glycoprotein	Role in virus entry	REF
BLLF1	Gp350	Binding to CR2\CD21 receptor in B cell	[12]
BXLF2	gH	Attachment of virus to epithelial cells, also essential for penetration to B-cells	[13]
BKRF2	gL	Heterodimer gH\gL is critical for entry into the host cell	[14]
BZLF2	gp42	Acting as co-receptor for fusion and entry of EBV into the B-cell	[15]
BALF4	gB	Required for fusion with both epithelial cell and B-cell	[16]
BLRF1	gN	It may play a role in post-fusion events	[17]
BBRF3	gM	Co-expressed with gN	[18]
BMRF2	BMRF2	Binding to host beta 1 integrin family and facilitates virus attachment to the epithelial cell	[19]

Lytic replication

Lytic replication leads to the production of infectious viruses. Lytic replication can occur in both B-cell and epithelial cells. The frequent replication cycle in B-cell occurs after reactivation from latency, while the replication cycle in epithelial cells initiates after entry of the virus [27]. For lytic replication of the viral life cycle, its genome must be linear [28]. In the latent phase, the genome is circular, so it should be linearized in the process of lytic reactivation [28]. During lytic replication, the viral DNA polymerase is responsible for the replication of the viral genome, but in the latent phase, it uses the host cell DNA polymerase to replicate its genome [26]. Three consecutive steps are involved in the production of lytic genes: intermediate early (IE), early (E), and late [29]. In the IE step, two essential genes BZLF1 and BRLF1, are expressed.

These genes act as trans-activators in activating the virus and initiating the cascade of viral genes expression [26]. Expression of the IE BZLF1 gene can induce a switch from latent to lytic infection. BZLF1 binds to the promoters of E genes and encodes proteins that are crucial for viral DNA replication. It recruits RNA polymerase II on their promoters and inducing the lytic cascade mechanism [29].

Expression of one of the BZLF1 or BRLF1 genes is enough to induce lytic replication in both epithelial cells and B-cells. The expression of one IE protein causes the expression of other proteins [30]. Early lytic gene products include a wide range of activities such as replication, metabolism, and blockade of antigen processing [31]. BNLF2a is one of the EBV viral genes expressed in the early lytic stage that plays an important role in escaping the virus from the immune system by expression of a 60 amino acid protein that interferes with antigen presentation to CD8+ cells [32-34]. Late lytic gene products often have a structural role, such as viral capsid antigen (VCA), which is involved in the production of the viral capsid. Several late lytic gene products such as BCRF1 are involved in escaping the virus from the immune system [35].

Latency

Unlike the lytic phase, progeny virions are not produced in the chronic phase, and it is a persistent viral infection. EBV persistent infection is mainly seen in memory B-cells but is also found in epithelial cells [36]. Actually, it is thought that one in the millions of B-cells can carry the virus genome as an episome or integrated DNA after recovering from an acute infection [6, 37].

During the latent phase, episome replication occurs by the host DNA polymerase. In the latency phase, only a limited portion of the genes are expressed [38]. These genes contain five EBV-encoded nuclear antigens (EBNA), two latent membrane proteins (LMP), EBV-encoded small RNA (EBER), and BART RNA (Table 2) [39, 40]. Three patterns of expression of latency genes exist that which of them have different expression patterns and are known as latency programs. Latency programs include latency I, latency II and latency III that each of which can lead to the expression of specific viral genes [41, 42]. Three latency program patterns have been determined in different Burkitt lymphoma and lymphoblastoid cell lines (LCL) and are reported in Table 3 [36].

Table 2: expression of Epstein-Barr virus latent genes

Latent gene	Roles	REF
EBNA-1	Responsible for DNA replication, mitotic segregation, EBV transcriptional activation, autoregulation	[36]
EBNA-2	Main viral trans-activator, critical for B-cell activation	[37]
EBNA-LP	Co-operate with EBNA-2 in viral and cellular gene transcription	[38]
EBNA-3A	With EBNA-3C block EBNA-2 by interaction with RBPG proteins, decrease expression of MYC	[39]
EBNA-3B	It is essential for B-cell transformation, tumor suppressor	[40]
EBNA-3C	Essential for efficient B-cell transformation, also like EBNA-2, LP and EBNA-3C regulates viral and cellular gene expression	[41]
LMP-1	B-cell and epithelial cell transformation, critical role as the primary EBV-encoded oncogene, and active NF-KB and P38 pathway, immune regulation	[42]
LMP-2A	Play a key role in improving cell adhesion, cell motility, and inhibition of epithelial cells also, can activation signaling pathways such as the PI3K\AKT, NF-KB, B-Catenin, STAT, and syk tyrosine kinase and immune modulation	[43]
LMP-2B	-	[43]
EBER	Play a key role in modulating innate immunity response, cell resistance to PKR-mediated apoptosis	[44]
BART	Immune regulation, cancer progression	[45]

Table 3: Epstein-Barr virus latency pattern

Gene expressed	EBNA-1	EBNA-2	EBNA-3A	EBNA-3B	EBNA-3C	EBNA-LP	LMP1	LMP-2A	LMP-2B	EBER	BART
Latency I	+	-	-	-	-	-	-	+	+	+	+
Latency II	+	-	-	-	-	+	+	+	+	+	+
Latency III	+	+	+	+	+	+	+	+	+	+	+

Epstein-Barr Virus microRNAs

The first human viral-encoded miRNAs were discovered in EBV in 2004 by Pfeffer et al. [43]. microRNAs (miRNAs) are small non-coding RNA containing about 20-22 nucleotides that play a crucial role in regulating gene expression [44]. For cell-to-cell transmission, miRNAs can be packaged into exosomes and released into the extracellular space [45]. various cell types can secreted exosomes into body fluids, including blood, urine, saliva, breast milk, cerebrospinal fluid, ascites, etc [46] miRNA plays an important role in the pathogenesis of EBV-associated cancers.

EBV encodes over 40 miRNAs, which are derived from approximately 25 viral-miRNA precursors [47]. Forty of them are located to BamHI-A rightward transcript (BART), and four are located to the BamHI fragment H rightward open reading frame 1 (BHRF1) [48]. These miRNAs have distinct levels of expression at different phases of latency. EBV miRNAs can modulate infection and pathogenesis by regulating the expression of viral genes [49]. The miRNA can be effective in escaping the EBV from the immune system by suppressing the release of pro-inflammatory cytokines, such as IL-12, and repress the differentiation of CD4+ T cells. miRNA directly targets the transported TAP2 and decreases levels of TAP1 and MHC class 1 molecule, which can cause the EBV-infected cells to evade CD8+ T cells [50].

Epidemiology

In developing countries, the infection occurs in children (in the first years of life), whereas in developed countries, it is usually delayed and seen in adolescence [51]. In some developed countries, however, the rate of infection is bimodal, with peaks in children under five years and again after ten years [52]. The cause of this bimodality is the transmission of the virus through oral excretion between parents and infants and from partners in adults [53]. The EBV antibody titer in seropositive individuals shows a U-shaped pattern, and the highest antibody titer is seen in infants and the elderly [54]. The high antibody titer in children is usually a reflection of primary infection and, in the elderly, is due to a reduced immune response [55, 56]. EBV has spread worldwide but with remarkable geographical variety in the distribution of EBV genotypes [57]. EBV contains two major types, I and II, that differ in the genes expressed in latently infected cells [58]. Both types are detectable all over the world, but type I is more common.

However, in some areas such as Africa, Papua New Guinea, and Alaska the second type is the most common [59, 60]. The prevalence of the virus is not significantly different between men and women, but overall, antibody titers are higher in women than men [53]. EBV is also associated with socioeconomic conditions. Poor socioeconomic status is related to primary EBV infections, whereas late primary EBV infection occurs more frequently in people with higher socioeconomic status [61].

Transmission

EBV usually is transmitted through oropharyngeal secretions. In adults and adolescents, the primary cause of virus transmission is kissing, whereas saliva on stuff such as toys or fingers is the primary cause of transmission among children. EBV is detectable in cervical secretions of 8-28% of young girls and adult women and also in the seminal fluid of men. In rare circumstances, the virus can be transmitted through breast milk. It can also be transmitted through blood transfusion and transplanted allogeneic hematopoietic cells or solid donor organs [53, 62].

Vaccine for EBV

Vaccination is the most effective way to avoid contracting EBV. More than 90% of the world's human population is infected by EBV, therefore, the vaccine is greatly important. The evidence shows that the EBV vaccine can prevent more than 200,000 new malignancies per year worldwide. gp350 viral antigen is the most abundant glycoproteins on the surface of EBV that known as the first candidate for the vaccine. gp350 has an important role in the efficient infection, although the gp350 deficient virions can still infect B cell, gp350 antibodies predominantly neutralize B cell infection. The amino-acid sequence of gp350 is extremely conserved among diverse strains, especially in the amino-terminal region, and 97% amino-acid similarity between EBV type1 and type 2 [63]. Among all EBV glycoproteins, gp350 is a promising vaccine target to block b cell infection and is also a target for T cell-mediated immunity (64-66). gp350 in combination with the AS04 adjuvant demonstrated can prevent the development of infectious mononucleosis (IM) after EBV infection [67]. Monoclonal antibodies against gp42 can inhibit EBV infectivity of B cells, while infection of epithelial cells inhibited by a monoclonal antibody against gH\gL or BMFR2 antigens [68, 69]. EBV neutralizing antibody titers correlate more with gp350 antibody compared with antibody titers to gp42 [70]. Furthermore, the latent antigen EBNA3A with tetanus toxoid formulated in water-in-oil adjuvant acts as a vaccine that is designated to induce EBV-specific T cell response. In almost 90% of vaccines, CD8 T-cell responses are obvious but can not prevent EBV infection. Although it seems that vaccination can reduce the incidence of IM [71].

Diagnosis

There is a spectrum of laboratory approaches for the diagnosis of EBV infection. The strategy of diagnosis is different between immunocompromised and immunocompetent individuals because therapeutic interventions in these groups are different. The diagnosis of primary infection is based on antibody assays [72]. Three serological patterns such as immunoglobulin (Ig) G and M antibodies to viral capsid antigens (VCA) and IgG antibodies to EBNA1 are a minimal requirement for detection of primary EBV infection. Immunofluorescence assay (IFA) is a gold standard for the diagnosis of EBV infection [73]. enzyme immunoassay (EIA) and chemiluminescence immunoassay (CLIA) are often performed as screening tests, while western blot analysis is used for confirmation [74]. For detecting and quantifying the virus in body fluids, polymerase chain reaction (PCR) analysis is the best approach, and tissue samples as well as, it can be used for measuring the viral load [75]. Additionally, the detection of EBV-encoded RNA transcripts (EBERs) by in situ hybridization is the gold standard for finding EBV in tissue [76].

Treatment

For the treatment of EBV infection, there is no approved antiviral medication. More physicians prescribe acetaminophen and non-steroidal anti-inflammatory drugs (NSAIDs) to alleviate fever and pain [77]. Fluids and nutrition are highly recommended, especially for febrile cases. Since most patients have anorexia in the first and seconds weeks, nutrition is very important [78]. Several antiviral drugs are used for EBV infection, although non specifically against EBV, and most of these drugs are nucleoside-analogue [79]. The only class of drugs that assess for EBV infection in clinical trials is nucleoside-like agents. The nucleoside analogue in the drug disrupts the synthesis of viral DNA by inhibiting viral DNA polymerase. Acyclovir is a nucleoside analogue that can reduce EBV shedding but without evidence of clinical benefit [80]. Studies have also reported the use of other agents, such as interleukin 2 [81], interferon-alpha [82], and Intravenous immunoglobulins (IVIg) [83] in the management of EBV related diseases.

EBV AND BURKITT LYMPHOMA

For the first time, Burkitt lymphoma (BL) was described 60 years ago by Denis Burkitt as a disorder with jaw tumors in African children, which he called “African lymphoma” [84, 85]. BL is an aggressive B-cell malignancy among non-Hodgkin lymphoma (NHL) types [86, 87]. It is divided into three classes, which vary in geographic distribution and relation with EBV: endemic (eBL), sporadic (sBL), and HIV-associated BL [85, 88].

- **Endemic BL** (eBL) is one of the most common childhood cancers in Equatorial Africa and is accounts for 75% of malignant disorders in children aged 4-7 years [89]. Evidence suggested a supportive relationship between EBV and eBL, which almost all eBL cases are associated with EBV [90]. Plasmodium falciparum contributes to the etiology of eBL first by disrupting immune response against EBV, thereby increase virus replication, second by stimulating B-cell activation, which leads to EBV lytic reactivation and abnormal expression of activation-induced cytidine deaminase (AID) that elevate the probability of MYC translocation triggering oncogenesis [91]. Jaw and kidney involvement are frequent, as well as the central nervous system (CNS), ileal, cecal, gonads, facial bone, thyroid, and breast can be affected [92].

- **Sporadic BL** (sBL) is almost occurring worldwide, without an association between geographic and climatic conditions. sBL is responsible for 1-2% of adult lymphoma, up to 40% of children’s lymphoma in western Europe and the United States. The abdomen, particularly the ileocecal region and lymph node, are the most common site of involvement. sBL is associated with EBV infection, ranging from 10-30% positivity in various regions [93].

- **HIV-associated BL** mainly occurs in human immune-deficiency virus (HIV) infection. HIV expansion in developed and developing countries has increased EBV-dependent BL in adult populations and is an early marker for AIDS progression in HIV-positive individuals [94]. EBV is observed in 30-40% of HIV-associated BL cases (Table 4) [95].

Table 4: Characteristic features of the various Burkitt lymphoma subtypes

	Endemic BL	**Sporadic BL**	**HIV-associated BL**
Geographical distribution	Equatorial Africa And Papua New Guinea	Worldwide	Worldwide
Incidence	$5\text{-}15\backslash 10^{5}$	$1\text{-}2\backslash 10^{6}$	Variable
Age	4-7 years	All ages	All ages
EBV-association	>90%	10-30%	30-40%
Co-factor	EBV, malaria	Unknown	HIV
Location of MYC breakpoint	More than 1 Kb upstream of first exon	Exon1 the MYC gene	Exon1 the MYC gene
Location of Ig breakpoint	Joining (j) region, Sμ switch region of Ig	Sμ, sα and j region	Sμ
Tumor site	Most common in the jaw, it can also occur in the abdomen, kidney, and ovaries	Most common in the abdomen, it can also occur in the kidney	Lymph node, bone marrow, abdomen, and CNS

The hallmark feature of all BL is the translocation of the MYC gene, which results in the upregulation of MYC protein. Most frequent translocation (approximately 80% of cases) between the MYC gene with a heavy chain of immunoglobulin (14q32). The two other translocations can be found in BL, translocation of c-MYC with the light chain of immunoglobulin at 2p12 and 22q11 [96, 97]. The c-MYC has essential roles in different cellular processes, such as regulates the transcription of various genes, cell growth, signal transduction, regulation of RNA processing, immune function, and apoptosis. MYC overexpression does not alone adequate to initiate lymphomagenesis. Dysregulation of microRNAs (miRNA) may lead to increase expression of MYC independent of chromosomal translocation or gene amplification [98].

Furthermore, in sporadic Burkitt's lymphoma, additional mutations related to the MYC gene have been discovered. Mutations in TCF3 or ID3, which is a protein that blocks TCF3 activity, are observed in about 70% of cases. In addition, almost one-third of sBL cases have a mutation in CCND3, which encodes cyclin D3 [99, 100]. sBL mostly causes abdominal tumors, while eBL is often present in the jaw and kidney but can also be present in the abdomen, ovaries, facial bone, and other extranodal sites [101, 102].

Burkitt's tumors have historically been monomorphic medium-sized cells with rounded nuclei, many nucleoli, and copious basophilic cytoplasm. Due to the presence of high numbers of macrophages, Tumours show a ‘‘starry sky’’ pattern [103]. The proliferation of BL cells is rapid, and their doubling time is 24-48 hours [104]. Their rate of apoptosis is also high. BL cells usually express B-cell markers including CD19, CD20, CD22, and IgM and germinal center markers such as CD10, BCL6, and human germinal center associated lymphoma (HGAL) protein [105]. The cell surface phenotype of BL cells reflects the origin of the germinal center, whereas jaw and ovaries are the primary sites of tumor growth, do not usually contain germinal center [106]. It seems that translocation of the MYC gene to immunoglobulin chains in eBL occurs during the VDJ recombination [107, 108]. This process occurs by a VDJ recombinase activating an enzyme called RAG-1/2 expressed in both pre-B and germinal center B cells [109]. However, in sBL and HIV associated, this chromosomal breakage happens mainly in the class switch region [110]. The GC involvement is an essential factor in the pathogenesis of this disease, whether in MYC translocation or association with EBV, malaria, and HIV infection as a co-factor [111]. Malaria and HIV infection, for example, has been determined to activate B cells [112]. Evidence from clonal EBV genomes in Burkitt's lymphoma tissues showing that the tumor is originated from a single infected cell. EBV gene products can directly aid cell survival in the BL cells. Both EBNA-1 and the EBERs, for example, have a function in BL cell survival and apoptosis prevention.

CONCLUSION

Burkitt's lymphoma is known as a highly aggressive non-hodgkin lymphoma with a diverse pattern of clinical presentation. It is a multi-factorial disease, although MYC translocation accounts for one of the main causes of its development. Other risk factors contribute significantly to MYC translocation. Finding the detailed role of each risk factor in the occurrence and progression of Burkitt's lymphoma is a good area in medical research. A better understanding of the detailed mechanism of Burkitt's lymphoma pathogenesis, as well as the precise role of each factor, can lead to the introduction of more effective prevention and therapy strategies.

EDITORIAL

About malpraxis, with love… for your information

Dan Mischianu

The title of this article for the Romanian Journal of Military Medicine, is inspired from the title of an American movie from 1967, ''To Sir with love'', starring Sidney Poitier in the lead role. Maybe some of you still remember it!... It is said that once, when school did not oscillate between "variable concepts" and "palpable realities", between protocols and procedures, a hydrogeology professor, in a practical work with his students, asked them if they knew the significance of the walnuts planted near the houses of the Romanian peasants. All the students were amazed by the question and kept silence. Nobody made any gesture. The professor knew that this would be the reaction of the students - because this was the answer to the following question: "Why does the world need teachers?" The professor answered the questions and taught the students, as much as a professor can teach, that ''a walnut needs plenty of water to grow and the roots of the walnut are very deep, and that is why houses that have walnut trees next to them will not have problems with dampness...''

This parable, as understood by our mind, aims on one hand to draw the reader’s attention to the fact that "malpractice is defined as an improper or negligent treatment applied by a doctor to a patient, which causes the latter any kind of harm, in relation to the degree of damage of his physical and mental capacity", according to DEX, and on the other hand to state that the "WALNUT" – that is, the Teacher, in the way he teaches his students will keep the "house" (i.e. the workplace) safe against possible future malpractice charges.

And after all, malpractice can even be compared to dampness... for any professional organization. A superb allegory! I consider it a proper allegory and that is why I wanted to introduce it to you.

Gral (R) Prof DAN MISCHIANU

Chief of Urology Clinic, Carol Davila University Central Emergency Military Hospital
Faculty of General Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

I do not pretend to be an expert in the field of "medical malpractice" but being involved and exposed to it in my daily activities, I welcome some considerations on this topic, which I have found out from books, from the media, and also from journalistic practice.

This article also wishes to draw attention of the medical community and to make it more aware of the responsibilities that we have when we dare to practice this noble profession. All of us – physicians, nurses, stretcher-bearers, technical staff – have civil liability (and here is the context of a possible allegation of medical malpractice), disciplinary liability (in the relationships we have as full members of our professional organizations) and criminal liability (most often as defendants, sometimes as investigated parties or as witnesses).

I will present you several cases that have been the subject of disciplinary, civil and criminal investigations, all of them in the “urological filed”.

Case 1

A 55-year-old patient is admitted in the Surgery Department for urgent mumps and blurred urine. Diagnosis at admission: ''Urinary infection. Prostate adenoma. Hematuria.” Diagnosis after three days since admission: ''Medium periurethral adenoma with urethral fistula microabs. Piohematuria. Urinary Infection." Under antibiotic treatment, the symptomatology improves and an open surgery is performed – with the patient's consent – practicing transvesical adenomectomy with favorable post-surgery progress.

14 days after surgery, the urinary incontinence at effort is detected, which subsequently worsens with the occurrence of episodes of urinary tract infection recorded on a posterior urethral stricture. Urethrotomy and TUR-P for remaining adenomatous tissue are performed within urological university department. The histopathological result revealed prosthetic adenocarcinoma microfocus and chronic urethritis. Unfortunately, the functional diagnosis is probative: High overall deficiency, Invalidity degree II.

The patient's complaint was lodged against the surgery after which the patient was diagnosed with urinary incontinence that can only be cured by means of an artificial sphincter costing about 5,000 euros and retirement due to illness.

The Superior Disciplinary Commission of the Romanian College of Physicians considered that the moment when surgery was performed and the surgical approach were inappropriate, therefore it decided to sanction the physician. [2]

Case 2

The son of a patient lodges a complaint against his family physician for the unauthorized delay of the diagnosis of his father's renal carcinoma. The physician treated him for a year and six months for macroscopic hematuria and a so-called renal colic. After one year and 6 months, the patient is diagnosed with renal neoplasm, he goes through surgery and dies one year later.

The Superior Discipline Commission analyzes the facts and notes the following: Hematuria is a diagnostic urgency and therefore its etiology needs to be confirmed as soon as possible by an urologist, the diagnosis of renal carcinoma is not the responsibility of the family doctor, therefore the applied sanction has remained in force.

Case 3

This is a case distinct from the others due to a capital error. It involves a 74-year-old patient admitted in a Urology department and diagnosed with: prostate adenoma, complete urine retention, prostate litiation. Twenty-four hours after admission, the urologist intervenes and performs transvesic adenomyctomy.

Immediate post-surgery progression is favorable with the subsequent occurrence of a third degree urinary incontinence. Two years after the surgery, the patient lodges a complaint against the doctor.

The Territorial Discipline Committee ordered the action to be discontinued, but the patient filed an appeal with the Supreme Discipline Commission. The latter did not find any irregularities neither in terms of the technique used nor of the complication that has arisen, not even regarding the postsurgery treatment administered by the urologist, that is, Driptane. The lack of the informed consent from the patient's file was the only and actually the capital irregularity found, for which the physician was sanctioned.

The medical deontology code in Romania is very clear: "for any diagnostic or therapeutic medical intervention, the informed consent of the patient is necessary". Moreover, the consent is given only after informing the patient about his/her diagnosis, prognosis, therapeutic alternatives, along with their risks and benefits. [2]

Case 4

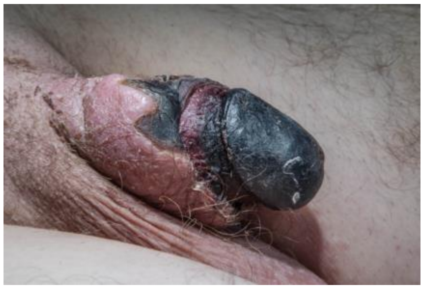
In the same spirit, there is also the case of a 39-year-old patient admitted in emergency with the diagnosis: right kidney colic. Two days after the admittance in hospital, surgery is performed: right pielolithotomy with internal drainage for calculus included in the right skin-ureteral junction and secondary uropionefrosis. The immediate post-operative progression was favorable up to the occurence of a cardio-respiratory stop during the first post-surgery night which was found to be irreversible. The cause of death was a massive pulmonary thromboembolism with probable causes either the lithotomy position, or more likely the presence of urinary sepsis.

The Superior Discipline Commission decided to sanction the physician for the lack of informed consent, lack of anticoagulation therapy and poor post-surgery follow-up [2, 3]

Case 5

The following is the case of a 54-year-old patient with a transient ischemic stroke, recently treated in a hospital from the country, where a Foley autostatic bladder ureter was mounted. From the patient’s personal history, we mention: type II diabetes, hypertension and ischemic heart disease. Approximately 8 (eight) days after urethro-bladder probe was mounted (according to the patient's report), physicians found the presence of an irreducible paraphimosis. Upon admission to the urology clinic, glandular necrosis, lack of local sensitivity, denuded penile body, penile scar tissue and necrosis, present at the base of the penis, free cutaneous mucous suture, skin remnants, cavernous body having an indurated appearance at palpation are found. The consultation of plastic and reparative surgery is entirely consistent with the urological clinical examination performed.

Figure 1: Preoperative aspect; the devitalization of the gland and the partially necrotic areas of the tegument can be seen



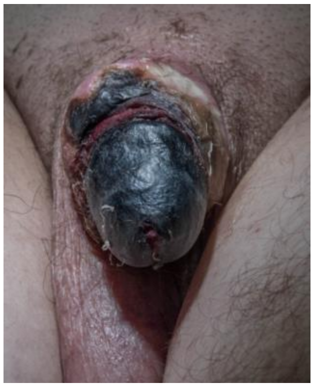


Figure 2: Postoperative final aspect; ureteral bladder and definitive perineal urethrostoma

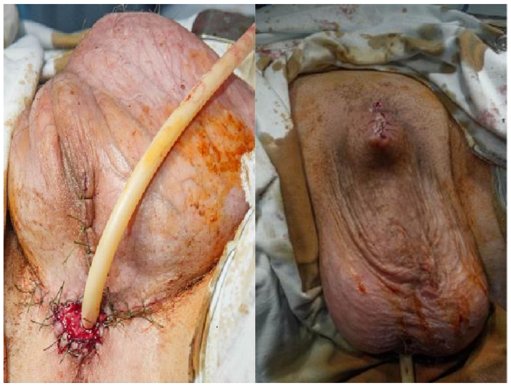

A surgical intervention is performed, after the patient gave his written consent, consisting of the following: noncrectomy, lavage, double drainage both by the uretro - bladder probe and by suprapubic cistostomy.

After limiting the infectious process, a new surgical intervention is performed consisting of definitive perineal urethrostomy and closure of the penile arch. Post-operative evolution is surgically favorable [4]

The patient contacted the media, the criminal investigation organs, the territorial discipline commission, and is in charge of the Superior Discipline Commission.

CONCLUSIONS

We wanted to point out, against all inconsistencies, errors, mistakes and malpractice, which perhaps appear at first sight incriminating up to the contrary proof, that the presence during the professional training of a ''Teacher'' of a “Walnut'' absorbing all ''professional dampness'' is defining for the next years of professional maturity.

In relation to all the exposed cases, some of them not so relevant anymore, others still ''incendiary'' on which the public opinion and the indigenous media keep a close eye, I believe this journalistic warning should give us all something to think about.

The old Romanian saying teaches us: "The good deed speaks for itself", but here, in Romania, there is a new saying which has been quoted for about thirty years, in my opinion without any substantial background, which says: "No good deed remains unpunished!"

However, I have the absolute conviction that although you have performed 10,000 perfect surgeries, if you make a mistake on your last day of surgical practice, that mistake will not be forgiven!

EDITORIAL

Academician Eugeniu Gh. Proca, founder of modern urology school in Romania. A memory

Dan Mischianu

Gral (R) Prof DAN MISCHIANU

Chief of Urology Clinic, Carol Davila University Central Emergency Military Hospital Faculty of General Medicine, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Motto: *"You only live once – but if you work it right, once is enough."* Joe E. Lewis

The history of Romanian Surgery will record, I am absolutely convinced, the name of Academician Eugeniu Gh. Proca (January 12, 1927 Godeni Muscel - 07.03.2004 Bucharest). As he testified in a televised interview, he wanted to become a general surgeon, he did not like urology at first, but in the end, as it happens in life, "you love who you live with." [1]

Image 1: Academician Eugen Proca at the age of great responsabilities and professional fulfilments

He didn't regret at all the fact that he became a Romanian urologist, transforming the Romanian urology to which he added new development opportunities; therefore the title of this article is perfectly true. Moreover, after many years, I can see that his first love – general surgery –seems to disappear as a stand-alone specialty, slowly but surely…

Urological surgery is a noble, beautiful, difficult and extremely consuming profession. As one of my colleagues, a surgeon from Constanta – Professor Vasile Sârbu – wrote: "The Romanian surgery amazed through two miracles. One of them happened at the end of the nineteenth century when, in two to three decades, starting from almost nothing, it came to the level of the brightest surgical schools in the world. The second miracle took place in the twentieth century and it refers to the ability to improvise, to do great surgery in all areas, under dramatic conditions, with instrumental, material and technology shortcomings. "[2] Perhaps the chance of Romanian surgeons was the fact that in the twentieth century the three Ministers of Health, who were surgeons, proved an exceptional organizational spirit in their mandates, (Acad. N. Hortolomei 1939-1940, Prof. Dr. Voinea Marinescu 1954 -1966 and Acad. Eugen Proca 1978-1985). I do not mention the name of Prof. Constantin I. Angelescu, a surgeon and a professor at Brâncovenesc Hospital and then at Filantropia Hospital because his ministerial mandate – excelent in substance! – took place at the Ministry of Public Works 1914-1916 and at the Public

Instruction.

Image 2. At the Hospital Prof. Dr. Th. Burghele (previously called Panduri) near his colleagues: primary urologists and secondary urologists

Having all the available means of information from the present, in which we all become when we want and especially when it is not the case, curious "researchers" in the biographies and in the personal identification numbers of everyone from everywhere, I do not want to present the commonly known things regarding the life and work of an overwhelming man, such as Acad. Eugen Proca, I only want to reveal some rather special information.

The professor was born on January 12, 1927, in Godeni, from the former county Muscel. He was a "trueborn inhabitant of Muscel", the only son of Gheorghe C. Proca and Maria Proca. The people from Muscel, who lived close to the mountains, are known to be fiery and combative spirits (see "partisans from Muscel"). Brilliant graduate of "Dinicu Golescu" High School in Câmpulung Muscel, he becomes a student of the Faculty of Medicine in Bucharest in 1945 and at the same time, a student of the Medical-Military Institute. This educational ambivalence has almost always been a solution for many skilled children coming from families with modest material conditions.

Image 3. Standing beside Acad. L. Gherasim and Gl. Prof. Dr. Doc. Iuliu Şuteu

I will tell you something that I saw with my eyes and I heard with my ears a long time ago. A very long time ago...

I was a student of the Medical-Pharmaceutical Institute (currently University of Medicine and Pharmacy Carol Davila, Bucharest) and a Corporal student at the Medical-Military Institute. By the kindness of the Party Secretary of the Medical-Military Institute, as I was a student with honorable academic achievements, in the summer session 1974-1975, I was allowed to prepare the exams to come, late at night, in a room which was more protected against the ubiquitous noise in the area of the North Railway Station. It was then that I discovered the catalogues of former graduates, in the room called "IMM Museum". There were large, thick-tatted books in a dusty cabinet. This is how I browsed, with curiosity, the catalogues of promotions of future military doctors, in which the high school photo was attached to each student. The promotions of 1940 and 1942 showed me the young and confident faces of the future generals and surgeon professors – Iuliu Suteu and Traian Oancea, once emblematic people for the Central Military Hospital. Looking at the pages which turned yellow over time, I was contradicted to find out at some point (it was midnight), the name Eugene Gh. Proca, Godeni, Muscel 1927 January, who entered the Medical-Military Institute in 1945 and below, across the whole sheet of paper, it was written with a red, thick pencil, I have such a vivid recollection of the word: "EXPELLED!".

Image 4. Minister Eugen Proca beside some of his collaborators

Years passed incredibly fast for all of us and while I was a secondary physician, studying my second specialty – urology, during a short break between two surgeries, I told the Professor what I had discovered 20 years before. We were living in difficult times, quite similar to the present ones, but I saw his unblinking blue-grey eyes shining and he even told me the story which was also mentioned by Dr. M. Mihailide in the footnotes of one of his books [3]. He said he had been expelled from the institute because he had lit the fire in a stove using the newspaper published by the party – “Scanteia” newspaper. He also mentioned the way in which, on a Sunday from April 1961, being on duty at the hospital, he took care with full empathy and unaltered human kindness of his former faculty colleague, who needed dialysis. He was uremic and only dialysis prolonged his life.

His faculty colleague was the one who had informed the State authorities about the fire lit in the stove!

Academician Eugen Proca was a Christian orthodox who believed in life after death and who, I am sure, is looking at us with empathy from up there. Academician Eugen Proca is not only the creator of the modern urology school from our country. He is and will always be an emblematic figure for Romanian surgery.

For as long as I was around him, in my perception he was a true "Imperator", intelligent to extreme, self-exigent, caustic with cheaters, tenacious, with a huge culture, always eager to self-improve and aware, at all times, that a surgeon's job does not have a program.

Anyone using a computer can easily find out about his scientific and clinical achievements: performing the first hemodialysis – April 7, 1959, World Health Day – at the hospital raised by the Professor or Academician Th. Burghele, performing the first kidney transplant in Romania in February 1980 (the operation for which he had been mentally and spiritually prepared for a very long time) and about his paideic model. What almost nobody knows is that when he was the second Minister of Health as term of office (7 years), he used to work 24/7. At six o'clock in the morning he was examining patients. Then he went in the surgery room. At 11.00 a.m. – 12.00 p.m., he went to his office from the Ministry where he tried to solve many problems of that time: the birth issue (which is now of almost no interest to anyone), the introduction of medical promotion contests and many more, and in the evening, at 8.00 p.m. – 9.00 p.m., he returned at the hospital to see his patients...

Apparently, Ceausescu’s wife was very proud of Minister Prof. Dr.Proca saying: “He is our only Minister who actually works.”

The fact that the name of Academician Professor Dr. Eugeniu Proca, 15 years after passing into a better and fairer world, is not found in the memory of some of our institutions, is an additional proof that the Latin parable "Nemo propheta in patria sua " (Luke's Book, Chapter IV, verse 24) or in English translation: "No one is a prophet in his country" remains forever and, unfortunately, perfectly true!...

It seems that Oscar Wilde also enlightened our understanding with the following aphorism: “the truth is rarely pure and never simple…”

I dared to reveal something from my own truth about the work and life of this Man.

REVIEW

A comprehensive review of the factors affecting the work-life balance of nurses

Alireza Rahmani[1], Moloud Radfar[1], Afsaneh Azarabadi[1]

Abstract: *The field of nursing has a lot of responsibilities and workload and is considered as a hard job. If a person does not have the spirit of being responsible for work or interest in service, he cannot survive in the difficult conditions that exist in the field of nursing, such as fatigue, work shifts, stress. Occupational concerns such as insufficient staff, high workload, long working hours and work pressure make nurses unable to play their role in front of their families. On the other hand, nurses are usually unable to perform their duties in the workplace due to family problems. In this study, related articles from the years 2000-2020 were reviewed. The results of studies showed that due to the importance of work-life balance in nurses, it is recommended that managers create the conditions for creating effective methods and techniques for job flexibility for nurses and help nurses to better perform these approaches with the necessary training. Taking care of nurses living conditions, question and answer sessions and interviews with nurses, establishing kindergartens with long working hours can also be effective in creating balance*.

Keywords: *work-life balance, nurse, management, satisfaction*

INTRODUCTION

Nurses are important members of the health care team that human society needs and they exert their influence in the health system by playing different roles [1]. For nurses, like other sections of the working community, the profession is considered as the most important factor in shaping social identity, the source of providing the family and shaping social relationships [2]. But despite all the positive effects that work and the resulting income have on the personal life of every human being, the concept of work has changed imperceptibly over time, exposing human social and family relationships to wide-ranging changes and causing problems for employed people [3].

One of the biggest problems that almost every working person complains about is the lack of balance between work and family activities, so much so that it can be said that the lack of balance between work and life has become a new companion for today's families [4]. Today, the nursing community around the world faces many problems such as insufficient staff, high workload, long working hours, irregular work schedule and work pressure. In studies on job stress over the past 32 years, the nursing profession has been considered as the first source of stress due to insufficient number of nurses and as a result of high work pressure on nurses [5]. Stress is a well-known component of modern nursing, which in the long run leads to chronic diseases such as hypertension, cardiovascular disease and asthma. In today's competitive world, the issue of work-life balance has attracted the attention of many researchers and academics around the world [6]. Today, the challenge of balancing work and family roles is one of the main concerns for individuals. They have the most and strongest connection with the individual and society, so that creating a balance between them is of great value and importance, and if the relationship between work and life is not managed, the conflict between them will cause irreparable damage to the individual, organization and society [7].

A study by Boston Consulting Group on HR managers across Europe found that balancing work and life is one of the three major challenges facing HR managers. Work-life balance is a self-identifying term that is achieved by a person who is able to manage responsibilities in the field of work and family, and this balance is maintained by physical and mental health by preventing grief and other negative effects on life [8].

Researcher shows that failure to achieve the right balance between effort and rest leads to a feeling of lack of control over workload and lack of energy to achieve individual goals and commitment, resulting in imbalance leading to fatigue, poor performance and reduced quality of life [9]. There are several definitions of work-life balance, with some studies defining work-life balance as follows: The extent to which an individual's effectiveness and satisfaction in work and family roles are consistent with his or her life priorities. Balancing work and life is one of the most important concerns of employees in organizations today. In other words, the most successful employees are those who can balance work and life [10]. One of the tools to balance work-family life is to create flexible programs in organizations. Hospitals are one of the organizations that have more justification for implementing flexible programs among their employees (nurses) [11]. The purpose of this study is a comprehensive review of the factors affecting the balance between work and life of nurses.

LITERATURE REVIEW

The Table 1 lists the most important studies conducted in the field of work-life balance.

Table 1: Literature review

Study specifications	Conclusion
Clark AJ. Nasica and fides. The Classical Quarterly. 2007 May;57(1):125-31.	Defines work-life balance as good and satisfying performance at work and at home, regardless of role conflicts (12)
Raisinghani M, Goswami R. Model of Work Life Balance Explaining Relationship Constructs. Int J Appl Innov Eng Manage 2014;3(2):46-59.	Work-life balance is defined as the satisfactory and appropriate performance of work at work and at home with minimal role conflict (13).
Littig B. Work Life Balance-catchword or catalyst for sustainable work? Vienna: Institute for Advanced Studies 2008.	On the other hand, work-life balance is mainly related to issues related to employee productivity, performance and job satisfaction (14).
Fapohunda TM. An exploration of the effects of work life balance on productivity. J Hum Resour Manage Labor Stud 2014;2(2):71-89	Various studies show that when employees are happy at home, workplaces are free of conflict and become enjoyable places that ultimately lead to increased employee productivity (15).
Engel CC, Bray RM, Jaycox LH, Freed MC, Zatzick D, Lane ME, et al. Implementing collaborative primary care for depression and posttraumatic stress disorder: design and sample for a randomized trial in the U.S. military health system. Contemp Clin Trials. 2014;39(2):310-9	Excessive workload and poor work environments severely affect the psychological aspects of employees and make it difficult for them to strike the right balance between work and private life (16).
Grzywacz JG, Frone MR, Brewer CS, Kovner CT. Quantifying work-family conflict among registered nurses. Res Nurs Health. 2006;29(5):414-26.	Hospital staff are more exposed to work-life conflict due to occupational conditions such as low organizational support, number of shifts, hard work, low work flexibility and long working hours (17).
Buerhaus PI, DesRoches CM, Dittus R, Donelan K. Practice characteristics of primary care nurse practitioners and physicians. Nurs Outlook. 2015;63(2):144-53	Long working hours in medical settings for nurses can cause severe depression and hormonal imbalances. As a result, nurses often tend to eat more, use drugs to relieve fatigue, stress, and drowsiness in their lives (18).
Kunaviktikul W, Wichaikhum O, Nantsupawat A, Nantsupawat R, Chontawan R, Klunklin A, et al. Nurses' extended work hours: Patient, nurse and organizational outcomes. Int Nurs Rev. 2015;62(3):386-93	Various studies show that nurses' mistakes at work, such as mistakes in injections and medication errors, cause more problems that may cause patients dissatisfaction (19).
Poulose S, Sudarsan N. Assessing the influence of work-life balance dimensions among nurses in the healthcare sector. J Manage Dev 2017;36(3):427-37.	Nurses also have responsibilities in relation to their family and social life, so that an imbalance between nurses' personal and professional activities can lead to reduced organizational commitment, burnout, increased work stress, severe job dissatisfaction and disruption in personal, family and life (20).
Konrad AM, Mangel R. The impact of work-life programs on firm productivity. Strategic Manage J. 2000;21(12):1225-37.	Balance programs in three types of organizations have significant profit margins, which are: organizations that have a high percentage of skilled labor, have made large investments in connection with the specific skills of their organization, and a high percentage of their workforce are women (21).

Study specifications	Conclusion
Wong SC-k, Ko A. Exploratory study of understanding hotel employees' perception on work– life balance issues. Int J Hosp Manage 2009;28(2):195-203	In their research, the factors affecting work-life balance are important, including having free time, work support in case of family problems, work commitment, job flexibility, attention to life issues and voluntary reduction of working hours in order to solve family problems (22).
Hasanqulipour T, Seyed Javadin S, Safiri K, Roshannezhad M. [Presentation and explanation of a model for causes and factors affecting the balance of work life]. J Public Adm. 2012;5(2):37-54.	In their research, they identified job flexibility, work and family support, and individual skills as factors affecting work-life balance (23).
Hasanqulipour T, Seyed Javadin S, Safiri K, Roshannezhad M. [Presentation and explanation of a model for causes and factors affecting the balance of work life]. J Public Adm. 2012;5(2):37-54.	Free time, work support, work commitment, job flexibility, attention to life issues and reduction of working hours voluntarily (24).
Rahimaghaee F, Dehghan Naiery N, Mohammadi E. [Iranian nurses perception of their professional growth and development]. Online J Issues Nurs. 2010;9(10).	In their research, they concluded that many nurses believe that in no other profession are conditions such as the nursing profession possible for them to help others, this attitude is largely rooted in the nature of Iranian society. Iranian society is associated with spirituality and religion, so that some nurses participating in the study of their presence in the nursing profession considered it a divine destiny that caused them to become closer to spirituality, so the commitment to the nursing profession regardless of material needs (25).
Hinami K, Whelan CT, Wolosin RJ, Miller JA, Wetterneck TB. Worklife and satisfaction of hospitalists: toward flourishing careers. J Gen Intern Med. 2012;27(1):28-36.	In their study, they showed that 1.63% of the nurses studied are weak in balancing work and life, which will lead to high job transfer rates, poor job satisfaction and ultimately low quality of life for nurses (26).
Hebrany P, Behdani F, Mobtaker M. [Exploring of stressors in nurses]. J Ment Health 2010;10(3):231-7.	The study identified job stressful factors for nurses including job insecurity, financial problems, communication conflicts, time constraints, irregular working hours, high work pressure, problems with psychological contracts, unequal job opportunities, inadequate vocational training and hospital policies. And introduced one of the ways to reduce these problems to support nurses (27).
Almalki MJ, Fitzgerald G, Clark M. Quality of work life among primary health care nurses in the Jazan region, Saudi Arabia: a cross-sectional study. Hum Resour Health. 2012;10(1):30.	In their study, they concluded that 91% of the nurses studied in the hospital environment need times or places away from patients to be free from any stress for hours (28).
Bahrami M. [Quality of life of nurses working in internal-surgical wards of Oncology center of medical university Isfahan]. J Isfahan Univ Med Sci. 2016;3(7):36-46.	In her research, she showed that the quality of life of nurses is far from the desired situation (29).
Baljani E, Rahimi J, Safari S. [Health Promotion Needs, Stress Resources, and Nurses' Workplace Problems]. J Hamedan Nurs Midwifery Fac. 2013;21(1):49-56	Showed that more than half of the nurses participating in the study needed help and promotion in the areas of exercise and physical activity, stress management, improving nutrition and avoiding continuous work (30).
Alhani F, Seyyed Nematollah Roshan F. [Explaining the Problems of Improving Nursing Healthy Lifestyle and Providing Solutions]. Razi Med J. 2014;21(125):1-8.	The biggest problem of nurses in promoting a healthy lifestyle related to the managerial-executive field was the high working hours of nurses with a score of 1.72 (31).

CONCLUSION

Considering the importance of nurses 'health as the main member of the country's health system, which is responsible for maintaining the health of themselves, family and society, and since nurses' health is directly related to the quality of their performance in caring for patients and playing family roles The importance of conducting this research in identifying the factors affecting the work-life balance of nurses is becoming increasingly clear. According to various studies in the present study, the factors affecting work-life balance, respectively, the importance of the effect, including job flexibility, commitment, work support, free time, attention to life issues and reduction of working hours were voluntarily extracted. Therefore, if hospital managers provide conditions for nurses to have some control over their working hours. In order to reduce the problems of nurses in this dimension, it is recommended that managers provide less working conditions for nurses in exchange for lower salaries and maintaining job security. This approach can be useful in solving many of the problems mentioned by nurses. The findings of this study emphasize the importance of creating a balance in the family and professional life of nurses, so that by informing the officials of the results of this study, an important step can be taken to reduce the problems of nurses and increase the quality of services provided to them.

Acute kidney injury incidence and models for mortality prediction in acute coronary syndromes

Madalina Moisi[1], Cosmin M. Vesa[1], Simona Bungau[2], Delia M. Tit[2], Raluca A. Corb Aron[1], Ovidiu Bratu[3], Camelia C. Diaconu[4,5], Marius Rus[6], Mircea I. Popescu[6]

Abstract: *Background and aim. The presence of acute kidney injury (AKI) in subjects diagnosed with acute coronary syndromes (ACS) represents a major predictor of a negative outcome.The purpose of this study is to reveal the incidence of AKI in ACS subjects and to illustrate the prognosis of these subjects, using special models for mortality prediction, based on the creatinine values and the presence of acute heart failure (AHF).*

Methods. Using multiple linear regression, several models were designed to predict the mortality including: comorbidities of the subjects, initial and highest value of the serum creatinine (sCr) during hospitalization, presence of theAHF and Killip class compared with sCr values, the last model illustrating the influence of all the previous variables.

Results. AKI had a significant incidence in the chronic kidney disease (CKD) group (53.11%). The mortality rate and the hospital readmission were higher in the CKD subjects (41.14%) versus the patients with normal kidney function (21.23%, p<0.01). The association of AKI and AHF, known as cardio-renal syndrome, was related to a negative outcome in the CKD group. The models for prediction of mortality emphasize that the age, dyslipidaemia, worst sCr, Killip class and AHF presence can be used to assess the mortality risk of patients with AKI and ACS. Previous pathological conditions such as diabetes, peripheral artery disease, coronary artery disease (CAD) and obesity, failed to achieve statistically significance for prediction of death.

Conclusions. AKI represents a serious pathological condition with a high prevalence in subjects with CKD; the association with AHF increases the risk of hospital readmission and fatal outcome.

Keywords: *acute coronary syndromes, acute kidney injury,acute heart failure, serum creatinine, predictors, mortality*

INTRODUCTION

AKI represents a pathological condition that resumes a complex interaction between various factors like subsequent renal failure, utilization of iodinated contrast substance during percutaneous coronary intervention (PCI), renal hypoperfusion caused by decreasing of the cardiac output during an ischemic event [1]. Manifestations of AKI may consist in a simple increase in sCr or severe renal failure with anuria requiring kidney replacement therapy [1]. There is a strong relationship between the renal function impairment and the CAD development, regardless the other common risk factor involvement. The prospective study realized by Jurkovitz et al. including 13,329 participants,

without previous CAD, reflected that increased values of baseline sCr (defined as ≥1.2 mg/dL in women and ≥1.5 mg/dL in men) were associated with a high incidence of acute myocardial infarction (AMI) and death due to ischemic events, compared to normal values of the sCr [2]. The renal impairment has an important influence on the patient's outcome during cardiovascular events and a small decrease in glomerular filtration rate worsens the prognosis of these patients [3].

The complexity of the atherosclerosis process in CKD subjects is a result of the interaction between common and uncommon risk factors. Diabetes mellitus, hypertension, dyslipidaemia and smoking represent essential factors in atherosclerosis development by promoting chronic inflammation, oxidation of the low-density lipoproteins and reactive oxygen species formation [4]. Even secondary hypertension in young persons has an important role in atherosclerosis occurrence and the level of plasma renin in these subjects represents a clear indication [5, 6]. Systolic and diastolic values of the blood pressure are strongly related to alimentation in young persons and there are several actions to change the unhealthy eating habits, beginning with education regarding healthy diet from early age [7].

Various terms were attributed to AKI and that is the reason why the comparison of studies is difficult. There are more than 30 definitions of AKI and the most used are: the Risk, Injury, Failure, Loss and End-stage renal disease (RIFLE), criteria revised by the Acute Kidney Injury Network (AKIN) and the Kidney Disease: Improving Global Outcomes (KDIGO) AKI Work Group classification.

AKI definition (according to KDIGO) expresses an increase in sCr by 0.3 mg/dL (≥ 26.5 µmol/L) within 48 hours or increase in sCr 1.5 to 1.9 times baseline value, with known or presumed abrupt onset within the prior 7 days. There are 3 stages according to the sCr values and the urine output. The first stage is consistent with sCr variations mentioned in the definition and a urine output of less than 0.5 mL/kg/h for 6-12 h, whereas the second stage involves increase in sCr 2.0 to 2.9 times baseline and a urine output of 0.5 mL/kg/h for 12 h. The last stage represents an association between increase in sCr to ≥ 4.0 mg/dL (≥ 353.6 µmol/L) or ≥ 3.0 times baseline or usage of renal replacement therapy and a urine output of less than 0.3 mL/kg/h for ≥ 24 h or anuria for ≥12 hours [8, 9, 10].

Usually, AKI remains undetected due to the fact that the onset is earlier in ACS patients and the sCr from admission represents the reference value, without actually knowing the evolution of the creatinine before hospitalization. If the sCr does not have a remarkable increase after admission, there may be an error of AKI diagnosis. New biomarkers able to early detect the AKI are required in order to initiate the preventive treatment and minimalize the renal insult [11]. The beginning of AKI is usually in the early phase of the ACS, fact that determines the late detection of this condition.

ACS represents a challenging diagnosis in CKD subjects because most of them remain asymptomatic. The explanation is suggested by the fact that uremic milieu and associated diabetic neuropathy influence the perception of pain in these patients [12, 13].Inflammation and oxidative stress represent common elements for both CKD and ACS, and the association of these diseases increases the risk to develop AKI. High levels of inflammatory markers (such as C reactive protein (CRP), fibrinogen and procalcitonin (PCT)) were found in subjects who developed AKI after PCI. Kurtul et al. revealed that PCT represents an independent factor for the development of AKI in ACS patients undergoing PCI [14]. Subjects without AKI emphasize PCT values less than 0.1 µg/L15. Gao et al. analysed 7000 PCI and illustrated that CRP levels were higher in subjects with AKI16. Gu et al. illustrated that determination of both markers, CRP and PCT, has higher predictive value in identifying subjects at high risk of AKI development. Also, the AMI is an independent risk factor involved in AKI occurrence [17].The role of antioxidants in the cardiovascular field is well known and vegetables/fruits consumption has demonstrated its effect for people at risk of cardiovascular diseases, on immunologic, clinical and antioxidant markers [18].

The main purpose of the present research is to highlight the incidence of AKI in ACS patients, and to present prediction for these patients based on particular models for mortality prognosis taking into account the presence of AHF and creatinine values.

METHOD

This study designed a retrospective single-centre analysis, which enrolled 435 patients admitted with ACS diagnosis in the Cardiology department of the Clinical Emergency County Hospital of Oradea, January 2016 - January 2018. The study lot involved 209 patients with ACS and CKD; the control lot comprised 226 patients with ACS and normal kidney function. The exclusion criteria included allergy to contrast media, exposure to the contrast media 2 days before the coronary angiography procedure, malignant conditions.The AKI patients were detected using the KDIGO classification because it contains lower values of sCr than the AKIN criteria, so the underdiagnosis of the condition was avoided.

ACS was revealed according to the Fourth Definition of the

Myocardial Infarction using the association of thoracic pain, elevated cardiac necrosis enzymes, electrocardiographic changes and imaging evidence of new regional wall motion disturbances.ST-segment elevation myocardial infarction (STEMI) was defined due to the presence of persistent ST-segment elevation more than 1 mm in two contiguous leads with the exception of precordial leads that require an elevation of 1.5 mm in women, more than 2.5 mm in men under 40 years-old and less than 2 mm in men older than 40 years. Myocardial infarction in subjects with previous left bundle branch was revealed due to Sgarbossa’s criteria. Non-ST-segment elevation myocardial infarction (N-STEMI) illustrates either a ST-segment depression ≥0.5 mm in two contiguous leads or deep inverted T wave more than 1 mm, along with elevated myocardial necrosis enzymes. Unstable angina (UA) expresses cardiac necrosis enzymes in normal limits associated with T negative wave, ST-segment depression or transitory ST-segment elevation [19]. Left ventricle ejection fraction (LVEF) was assessed using the Simpson’s method. The normal value was considered between 50-72% in men and 52-74% in women [20].

Cardiac necrosis enzymes, cTnI (cardiac troponin I) and hscTnI (high-sensitive cardiac troponin I), were tested and abnormal values were defined as elevated when the result showed at least one value above the upper limit of the 99th percentile. Normal ranges were considered whenthe values were lower than 0.04 ng/mL for cTnI and 29 ng/L for hscTnI. Serial measurements were required to exclude thediagnosis of myocardial injury [21].

Killip Kimball classification was assessed in each patient with STEMI and the four classes. The first class illustrated subjects without signs of cardiac decompensation, the second class included patients with rales, third heart sound and increased jugular venous pressure. The third class was consistent with acute pulmonary oedema and the last stage revealed subjects with cardiogenic shock [22].

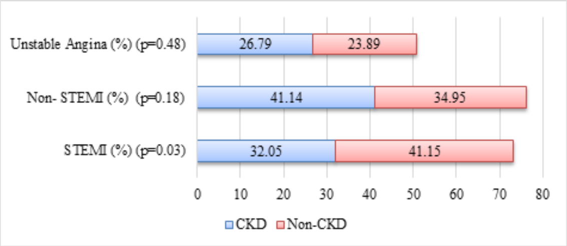
The statistical analysis was performed using Biostat software. Chi-square test was used when comparing prevalence in the two-groups, while Anova test was used to compare the mean values of certain parameters in the two groups. Univariate and multivariate regressions were done to assess the factors that correlate with the risk of death. A value of p<0.0 was considered statistically significant.

This research was performed respecting the World Medical Association Declaration of Helsinki (Ethical Principles for Medical Research Involving Human Subjects), and it was approved by the Ethics Committee of the Clinical County Emergency Hospital of Oradea, Bihor County, Romania (decision no. 30088/December 10th, 2019); each patient included in the study signed the informed consent form.

RESULTS

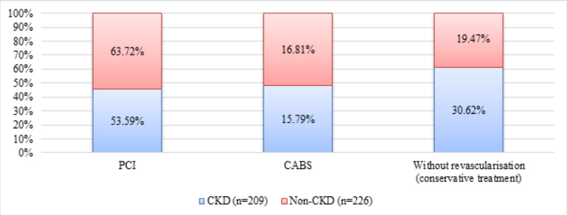
The prevalence of the common risk factors and associated comorbidities was higher in the CKD lot. Conditions like hypertension, diabetes mellitus, dyslipidaemia and peripheral artery disease were present in an increased proportion in CKD subjects in comparison with patients without CKD (84.21% vs 63.27%, p<0.01; 58.85% vs 33.62%,p<0.01; 60.09% vs 49.95%, p=0.02; 20% vs 4.9%, p<0.01).The distribution of the ACS types was different between the two lots. STEMI was characteristic in subjects without CKD whereas the CKD lot revealed mostly N-STEMI cases, UA had a similar incidence in both CKD and non-CKD lots (Figure 1).

Figure 1: Categories of coronary syndrome according to the presence/absence of CKD



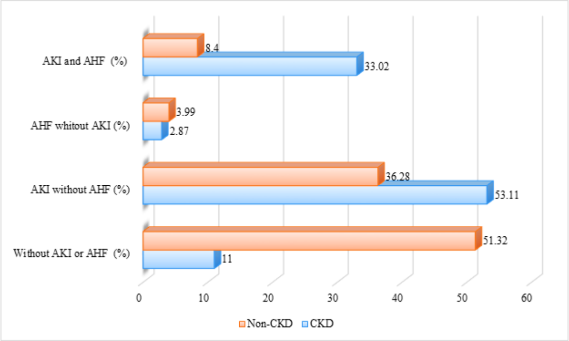
Myocardial interventional revascularization through PCI and stent implantation represented the therapeutic option for 53.59% of CKD subjects and 63.72% non-CKD patients (p=0.03). Coronary artery bypass surgery (CABS) was performed in 15.79% of CKD subjects, whereas the non-CKD lot had a proportion of surgical myocardial revascu1arization of 16.81% (p=0.77). The use of conservative treatment instead of PCI, known as renal nihilism, was objectified mostly in the CKD lot (p<0.01) (Figure 2).

Figure 2: Treatment of ACS according to the presence/absence of CKD



AKI has occurred in the CKD lot, revealing statistically significance (p<0.01). The association of two pathological conditions, such as AKI and AHF, had a major impact in subjects' outcome and was revealed in the CKD group (p<0.01). The uncomplicated evolution of the ACS cases was noticed in patients with normal kidney function (p<0.01) (Figure 3).

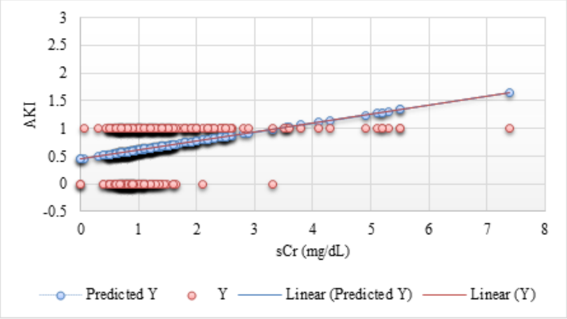
Figure 3: Presence of AKI or AHF according to the presence/ absence of CKD



Deteriorated LVEF was noticed in a higher proportion in CKD lot, compared to patients without CKD (23.5% vs 20.17%, p=0.4). The average value of sCr was higher in the CKD lot (1.66 mg/dL vs 0.8, p<0.01), the standard deviation (Q1=1.01, Q2=0.20). Another important parameter was the worst value of the sCr which revealed a high level in the CKD lot with statistical significance (2.71 mg/dL vs 1.1 mg/dL, p<0.01), standard deviation (Q1=2.11, Q2=0.36).The analysis of the average sCr variation illustrated an increased value in the CKD group (1.03 mg/dL vs 0.3 mg/dL, p<0.01).The mortality rate was statistically significant in CKD subjects compared to patients with normal kidney function (13.39% vs 6.1%, p<0.05, SD CKD 8.39-17.61, SD non-CKD 4.39-7.69). Killip class assessment revealed that most of the subjects without CKD had first Killip class at admission (p<0.01), whereas the CKD patients were included in the third and fourth Killip classes (p<0.01).

The initial value of sCr illustrated importance in univariate analysis and predicted the development of AHF and AKI (p<0.01) (Figure 4, Figure 5, Table 1).

Figure 4: Correlation between worst value of sCr (mg/dL) and AKI development



Models for mortality prediction were designed using multivariate analysis and including different factors to demonstrate the impact of AKI and other comorbidities or biomarkers regarding the outcome of patients with ACS (Table 2). The first model, based on the medical history and the associated cardiovascular risk factors of the subjects, illustrated that only the age and dyslipidaemia reached statistical importance to predict the mortality risk in ACS subjects with and without CKD (p=0.0404, p=0.0332).

Figure 5: Correlation between worst value of sCr (mg/dL) levels and AHF development

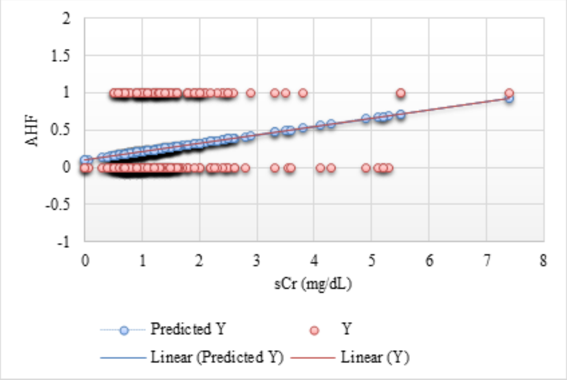


Table 1: Parameters of linear regression

	Coefficient	Standard error	LCL	UCL	t Stat	p value
Between worst value of sCr (mg/dL) and AKI						
Intercept	0.4489	0.0389	0.3724	0.5253	11.5427	*0.0000
Worst value of sCr (mg/dL)	0.1619	0.0263	0.1102	0.2136	6.1518	1.7451E-9
Between sCr (mg/dL) and AHF

Worst value of sCr (mg/dL)	0.1120	0.0238	0.0652	0.1587	4.7053	3.4162E-6

**p<0.05, respectively p<0.001; LCL –low confidence limit; UCL–upper confidence limit; sCr – serum creatinine*

Diabetes, hypertension, smoking condition, history of peripheral artery disease, stroke did not predict the risk of death in the presented model. The second model included an analysis regarding the mortality risk of the study groups based on the presence of complications and biomarkers values. The presence of AHF and Killip class were statistically significant in anticipating the fatal outcome (p=0.0002, p<0.01). Other parameters like sCr value, age, troponin, LVEF failed to demonstrate their role in predicting the mortality. The third model evaluated the difference between baseline sCr and the worst value of sCr in identifying the patient's outcome. The worst value of sCr was the most important factor in mortality prediction in this model (p=0.0117). The fourth model represented an evaluation of all the variables in detecting the mortality risk. The Killip class and the AHF demonstrated statistical importance (p=0.0132, p= 0.0000).

DISCUSSIONS

The present study outlines two significant ideas: (1) The serial determination of sCr is essential in identifying subjects with AKI and special attention should be paid to subjects with CKD undergoing the coronary procedure; (2) The presence of AKI in patients with ACS and CKD can be a fatal prognosis, especially when associated with AHF. Despite following accurate indications regarding coronary imaging, like the use of a low-osmolarity contrast agent (600-800 mOsm/kg) and the corresponding post-procedural hydration associated with diuresis stimulation, the incidence of AKI varies from 5% to 55% [1, 23, 24]. The variable incidence resides in variations of the nomenclature of this term [25].

As there is no safe and highly efficient prevention method for AKI, it is considered necessary to develop prediction scores to identify high-risk patients [26]. A first element that should be included is the Killip class, evaluated upon admission to the hospital, along with the presence of AHF. These elements should be identified particularly for CKD subjects, as multivariate analysis demonstrates the role of independent risk factors for the risk of death in these patients. The reduction of the number of functional nephrons, evidenced by the initial sCr analysis and the worst value of the sCr, together with an increased rate of reduced

LVEF are major predictors of AKI and AHF occurrence, an association known as cardio-renal syndrome [27].

Common cardiovascular risk factors have failed to outline the risk of mortality in multivariate analysis, except for dyslipidaemia, since in the case of CKD there are also factors specific to the uremic environment that significantly influence the prognosis of these patients. Early myocardial revascularization reduces the risk of AHF. A recent study confirms the importance of this therapeutic method, especially in subjects with N-STEMI and CKD, that associate increased values of cardiac biomarkers, such as the N-terminal fragment of the brain natriuretic peptide (N-terminal pro b-type natriuretic peptide, NT-proBNP, BNPT) or hscTnI, or a Killip class three or four [28]. For patients with ACS undergoing PCI, an independent predictor of developing AKI is the level of NT-proBNP at admission, being connected with high costs, extended hospitalization, high rates of terminal-stage renal failure, repeat revascularization, myocardial infarction and early and late mortality [29]. LVEF shows low values in subjects with ACS and CKD due to the increased incidence of multivariate CAD and especially to the impairment of left coronary artery trunk. Choosing the method of myocardial, interventional or surgical revascularization should consider the possibility of resolving all significant coronary lesions, the complexity of CAD and the surgical risk for the subjects [30].

The increased mortality evidenced in the group of subjects with CKD is explained by the increased incidence of AKI in these subjects. The mean hospitalization period was longer for patients with ACS and CKD who developed AKI, highlighting the severity of this complication (15.71 days vs. 13.15 days, $p < 0.01$). For patients with STEMI, accentuated oxidative stress, sympathetic activation and pronounced inflammatory response were found to synergistically accelerate AKI [31]. The most powerful independent predictor of mortality within hospital in case of dangerous settings like for STEMI associated with cardiogenic shock was identified to be AKI [32].

A recent and further argument of the way AKI influences the long-term effect for patients suffering from STEMI subjected to primary PCI is presented by Narula et al. The 3-year follow-up revealed that the mortality rate for patients suffering from AKI was 16%, while for those without AKI it was 4%. As for the association of severe ischemic cardiac side effects and serious bleeding, the intensification of the side effects was more accentuated after three years, being of 40% for subjects with AKI and about 25% for patients without AKI. Corroborated, these data show that AKI evolution influences the complete prognosis of ACS patients [33]. Throughout primary PCI for STEMI, increased contrast volume is connected with increased levels of AKI and mortality, the contrast ratio and contrast volume determining AKI evolution [34]. A general complication in the case of patients suffering from shock and myocardial infarction is nephropathy, as recently revealed by a CULPRIT-SHOCK study that showed a high percentage of subjects (11.6-16.4%) who needed renal replacement therapy [35].

The decrease of renal mass is thought to be the main pathophysiology that is associated with CKD, AKI and the end stage renal disease. Considering these interesting findings and the fact that the common therapies do not influence the short-term prediction in AKI, supplementary preventive actions meant to ameliorate the health status for AKI survivors are extremely important. There is general evidence that most of the patients suffering from AKI are not regularly surveyed by nephrologists and the current clinical practice does rarely include follow up evaluation for AKI, dealing with this issue representing a considerable option for important change and better caring for this category of population [36]. Even patients with mild and moderate AKI, which in most cases is short lived and clinically reversible renal failure, had an elevated risk of death after hospitalization that did not dissipate over time. These conclusions arenovel and do not support the conventional teaching that AKI in its mild-form is inconsequential [37].

CONCLUSIONS

AKI negatively influences the short- and long-term prognosis of subjects diagnosed with ACS. CKD and AHF are other negative predictors of ACS evolution and their association with AKI has shown the highest mortality rate. Although it is not an accurate marker, the initial sCr and the worst value of sCr can be used in AKI detection to establish appropriate therapeutic measures. New predictive scores able to identify AKI in a timely manner are necessary, considering the fatal prognosis for patients with ACS and CKD.Early and complete myocardial revascularization in ACS is an optimal method, which decreases the risk of developing AHF and AKI, known as cardio-renal syndrome.

Addressability to the Emergency Department of patients with acute post-COVID 19 clinical symptoms

Silvia Nica[1,2], Adriana Albu[1], Remus Nica[3], Catalina Ciornei[1,2], Florina Cofaru[1,2], Irina Eremia[1,2], Danut Cimponeriu[4]

Abstract: *The long-distance post-SARS-CoV2 infection effects were partially known. The study aims to follow the evolution of the patients with acute post-COVID 19 clinical symptoms presented in the Emergency Department. Methods: We analyzed 262 presentations more than 14 days after the initial COVID-19 diagnosis and with at least one acute COVID-19-related symptom. This study included presented between 01.01 and 31.05.2021 in the Emergency Department of Bucharsti-Emergency University Hospital. Data were obtained in real-time, at the presentation, from the patients' medical charts, and afterward from SUUB's database. Results. Out of the total of 262 presentations, 40.84% required patient hospitalization. The highest number of presentations with (18.70%) or without (22.90%) hospitalization was recorded in the first month after the COVID-19 diagnosis. Patients with less than 30 days between presentations had significantly fewer hospitalization days, compared to those with more than 30 days between presentations (8.3 vs 14.14 days, p=0.009). We found a high amount of hospitalization days (1093 days), with 29.88% deaths. Conclusions: COVID-19 complications require prolonged hospitalization, with implications on the patients' quality of life, the overcrowding of intensive care facilities, high-cost treatment, and unfavorable evolution for a great number of patients.*

Keywords: *long COVID, ongoing COVID, COVID-19 complications, hospitalization*

INTRODUCTION

Worldwide, the Emergency Departments were at the front line of the fight against the SARS-CoV2 pandemic, which began on March 11, 2020 [1]. Presently, there are published many COVID-19 studies, which bring information regarding the physiopathological mechanisms of action, the long-term effects, and complications of the disease, treatment, and the potential leverage of prevention, as well as the psychologic and socio-economic implications of COVID-19 [2]. Males seem to be more frequently affected by COVID-19 whereas the risk for poor prognosis is increased by age and chronic illnesses [3]. These factors seem to contribute to the extreme variability of COVID-19, from asymptomatic to severe illness and death, as well as to its unpredictable response to treatment.

In the Czech Republic, a study over 2 ½ months, that enrolled 7,455 patients with positive RT-PCR SARS-CoV2 tests shows that 15.9% required hospitalization and 6.2% developed severe complications [4].

The term "ongoing symptomatic COVID-19" is used when the symptoms persist between 4 and 12 weeks whereas the frequently used terms "post-COVID syndrome" or "long COVID" implies the persistence of symptoms over 12 weeks, in the absence of other causes [5,6]. The Office for National Statistics (UK) estimates that 1 of 10 persons with positive COVID-19 tests has symptoms for a period of more than 12 weeks, and 1 of 5 persons for a period of more than 5 weeks. In England, an ample review of 508,707 COVID-19 patients identified several risk factors for the persistence of symptoms for more than 12 weeks (e.g. age, female gender, obesity, and hospitalization for COVID-19) [7].

[4] University of Bucharest, Bucharest, Romania

conducted on patients discharged from a hospital in Rome with "ongoing COVID-19 symptoms". Of them, 87% had at least one symptom present 60 days after the debut of SARS-CoV2 infection, 55% had 3 or more symptoms, and 40% had a reduced quality of life [8].

NHS England estimated that out of 95,000 patients admitted to hospitals until June 5, 2020, 45% had "ongoing support" and up to 50% required rehabilitation services [9].

Long COVID affects multiple and different body systems, influences daily routine activity [10], impacts family life, and decreases workplace productivity, with psychological and socio-economic repercussions. A study that followed 3,762 patients from 56 countries, which had symptoms for more than 28 days, showed that 90% of them had symptoms for up to 60 days and 91% needed more than 35 weeks to recover; the most frequently reported symptoms after 6 months were fatigue, decreased resistance to exertion, and cognitive disfunction [11].

Persistent clinical charges for up to 6 months after COVID-19 were reported mostly for inpatients, but also for those who did not require hospitalization [12]. A cohort of patients, discharged in the period 07.01-29.05.2020, mentioned fatigue, weakness, sleeping disorders, anxiety, and depression, 6 months after acute infection [13]. The persistence of symptoms (e.g. fatigue, shortness of breath, memory loss, hair loss) was correlated with the number of days of hospitalization [14]. A New York City study that evaluated 929 survivors out of 1,190 hospitalized COVID-19 patients at 3 months and 6 months after discharge, found the persistence of cardiopulmonary symptoms (35.7%, respectively 28%), especially shortness of breath (22.1%, respectively 15%). After 6 months from discharge, general (26.4%) and neurological (24.2%) symptoms persist. There were also 33 deaths during the 6 months [15]. A study conducted in Rome, on 143 patients, shows that a high number of patients still have more than 2 symptoms at discharge. The patients entered a recovery program after discharge and, after 60 days from the debut 12.6% had no symptoms, 32% had 1-2 symptoms, and 55% had more than 3 symptoms [16].

A review of 24 articles published until 01.01.2021 concludes that the presence of more than 5 symptoms in the first week of acute infection is associated with the development of long COVID, regardless of age or gender. Increased risk of symptoms' persistence is associated with advanced age, hospitalization at the debut, shortness of breath at debut, chest pain, and comorbidities [17].

Hypertension, considered independent or in association with diabetes mellitus, predisposes to longer persistence of symptoms [18] and the increased mortality after COVID-19 [19]. COVID-19 also is a risk factor for other diseases, like stroke, myocardial infarction, and thrombosis [20].

Taking all this info into account, we followed the patients with previous COVID-19 diagnoses presented, in the Emergency Department of the University Emergency Hospital in Bucharest (SUUB).

METHOD

We analyzed 262 emergency presentations, unique or multiple, in the period January-May 2021, with at least one acute COVID-19 related symptom, that necessitated or did not hospitalization. Clinical data were obtained in real-time, at the moment of the presentation and afterward, from SUUB's database.

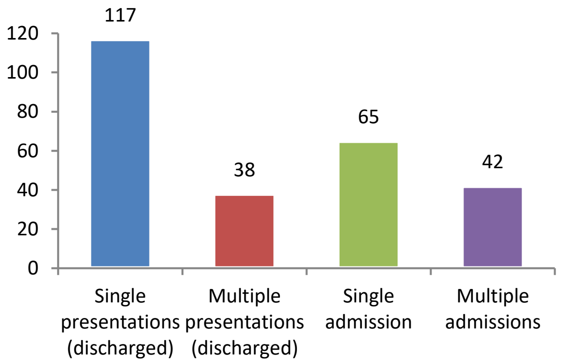
Inclusion criteria were: at least 14 days after prior COVID-19 diagnosis, confirmed by RT-PCR test, age over 18 years, and the presence of at least one persistent, acute, or newly appeared symptom associated with SARS-CoV2 infection. Presentations in Emergency Department that are not related to the previous COVID-19 diagnosis were not included in this study.

Statistical analysis was performed using the StatsDirect software.

RESULTS

The total number of presentations with acute post-SARS-CoV2 infection symptoms in the Emergency Department of SUUB was 262 (Figure 1); out of these, 155 (59.16%) were discharged and 107 (40.84%) were hospitalized.

Figure 1: Total number of presentations (262) in the period 01.01.-31.05.2021



117 patients didn't need hospitalization, and 2 of them had 2 presentations. 87 patients were hospitalized; out of these, 65 patients had a single presentation with admission and the other 22 patients had multiple presentations (in total 78

presentations) out of which 42 presentations were followed by admission, and 36 by home discharge (Figure 1).

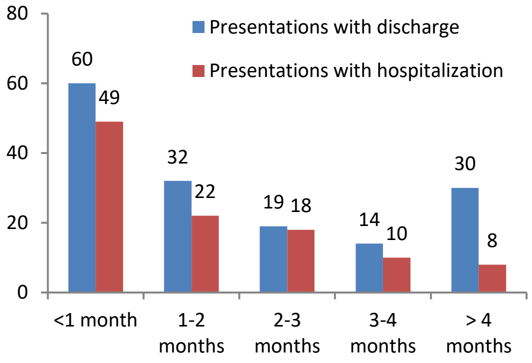
There is a high variability regarding the 22 patients with multiple presentations, as follows: 12 patients with 2 presentations, 1 patient with 3 presentations, 7 patients with 4 presentations, 1 patient with 8 presentations, and another with 15 presentations, all of them with at least 1 admission.

Most presentations are in the first month after the initial diagnosis, regardless of severity: 60 presentations with discharge (22.90%), and 49 presentations with hospitalization (18.70%).

The decreasing trend is maintained at 4 months distance for both types of patients and continues after 4 months for the patients that needed hospitalization.

There is an increase in presentations that do not require hospitalization, with less severe symptoms, like fatigue, decreased resistance to exertion, sleeping disorders, physical and mental asthenia, influencing daily activity, after 4 months from the COVID-19 diagnosis (Figure 2).

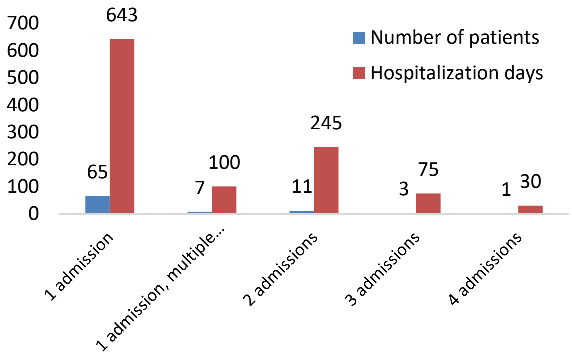
Figure 2: Interval between COVID-19 diagnosis and ED presentation



Concerning the time of hospitalization, there is high variability, from 1 to 36 days. The 65 patients with single presentation and admission cumulate a total of 643 days of hospitalization.

In the case of the 22 patients with multiple presentations, they have a variable number of hospitalizations and hospitalization days, as follows: 7 patients with 1 hospitalization (5-36 days), 11 patients with 2 hospitalization periods (6-46 days), 3 patients with 3 hospitalizations (15-31 days), and 1 patient with 4 hospitalizations (30 days). The total number of hospitalization days for all the patients in the study was 1093 days (Figure 3).

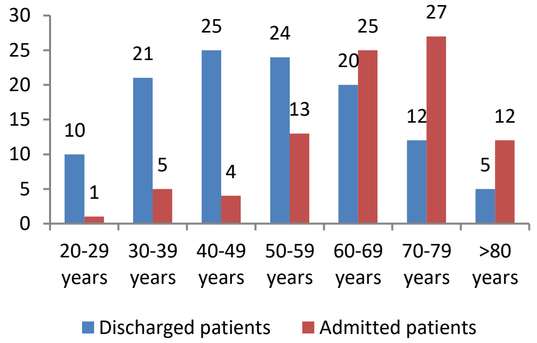
Figure 3: Number of presentations with admission and hospitalization days



The analysis of the sublot of patients with multiple presentations and admissions shows that the average value of hospitalization time for presentations in the first 30 days from COVID-19 diagnosis is 8.3 (±4.5) days, respectively 14.14 (±4.98) days for presentations after the first 30 days (0.01). Out of the 87 hospitalized patients, 61 (70.12%) were discharged, and the rest 26 (29.88%) died.

The 117 patients that didn't require admission were 63 (53.85%) males and 54 (46.15%) females. The highest age group was 40-59 years, respectively 49 patients. There were no patients aged less than 20 years. 5 patients had between 80-89 years (Figure 4). The most frequent symptoms for the discharged patients were: respiratory (36.77%), cardiac (19.35%), digestive (18.06%), neurological (18.06%), ENT (4.52%), anxiety (3.23%).

Figure 4: Age distribution for discharged/admitted patients

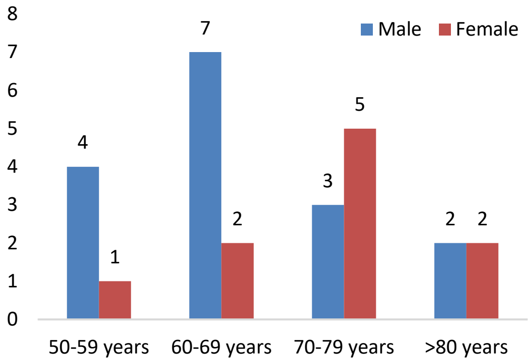


Out of the 87 admitted patients, 16 (18.39%) males and 10 (11.49%) females died. Most deaths occurred in men (43.75%) aged 60-69 years and in women in the age group 70-79 years (50% of female deaths) (Figure 5).

Out of 107 admissions in the period covered by the study, 46 patients (43%) had a positive RT-PCR test at the time of admission. During hospitalization, 15 patients (32.6%) from this lot; 11 patients (18.03%) of the 61 patients with negative

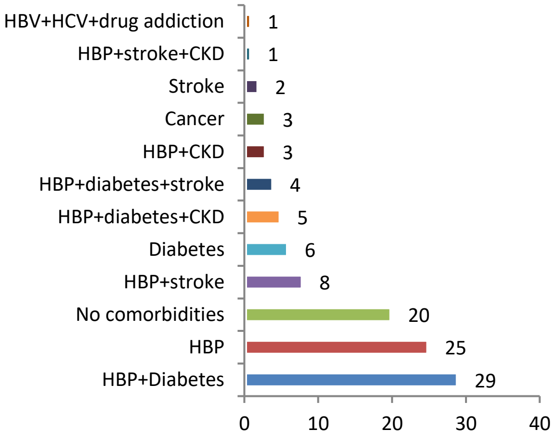
RT-PCR at the admission died (p>0.05).

Figure 5: Age distribution for deaths



Out of the 22 patients with multiple admissions, only 8 had positive RT-PCR at first admission (5 of them had 2 admissions and 3 patients had 3 admissions). The other 14 patients had negative RT-PCR tests. Eighty-seven patients (81.30%) had comorbidities versus 20 patients (18.69%) without comorbidities (Figure 6). The most frequent conditions diagnosed at the admission of patients needing hospitalizations were an acute respiratory failure (25.68%), stroke (22.47%), acute decompensated heart failure (6.42%), Clostridioides difficile infection (6.42%), acute coronary syndrome (5.35%), pulmonary thromboembolism (4.28%), and deep venous thrombosis (4.28%). Out of the deceased patients, 5 (25%) had no medical history before the SARS-CoV2 infection, 2 males (53 years and 68 years old), and 3 females (68, 70, and 81 years old).

Figure 6: Comorbidities in hospitalized patients



Neutrophilia was found in 66.5% of patients with a single presentation. History of stroke, neutrophilia, heart rhythm disorders, and neurological diagnoses at admission presented significant differences between patients stratified according to the number of presentations (Table 1). The most deaths were in patients with a single which suggests the severity of the post-COVID 19 pathologies.

Table 1: Differences identified between subjects who required hospitalization (n=87)

Characteristics	Number of hospitalizations		Statistical significance (p)
	Single	Multiple	
Neutrophilia (normal/yes)	22/43	14/8	<0.05
History of stroke (no/yes)	46/19	20/2	<0.05
Neurological diagnoses at admission (no/yes)	44/21	20/2	<0.05
Heart rhythm disorders	18/47	0/22	0.002
Discharge/Death	43/22	21/1	0.004

DISCUSSION

In the third wave of the pandemic, at the same time with newly infected COVID-19 patients, there were 262 post-COVID presentations in the Emergency Department, in the first 5 months of the year 2021.

Out of these, 59.16% of presentations did not require hospitalizations, and 40.84% were hospitalized. For both categories of patients, most came to the hospital with acute or persistent symptoms in the first month after the initial COVID-19 episode. 22 patients came repeatedly to the ED, out of which 7 patients had 4 presentations, 1 patient had 8 presentations and 1 patient had 15 presentations.

The patients presented in the first 30 days after SARS-CoV2 infection had significantly fewer hospitalization days, versus those presented after 30 days or more (8.3 vs 14.14 days, p=0.01).

The number of hospitalization days is variable, from 1 day to 36 days, for a single admission. 15 patients (17.24%) required multiple hospitalizations (2-4). Four of these patients cumulated over 30 days of hospitalization (maximum 46 days for 1 patient). The total number of hospitalization days for an small number of patients (87) was 1093.

Out of the total number of admissions, those with negative RT-PCR tests at the time of admission were more (57%) than those with positive RT-PCR tests. 18.03% of patients with negative RT-PCR died, vs 32.60% of those with positive RT-PCR. The results show that a negative RT-PCR test after the initial COVID-19 episode isn't equivalent to favorable evolution or total recovery.

Our study, like other studies, argues that associated comorbidities increase the risk of COVID-19 symptoms' persistence, the risk of complications, and is a factor in poor prognosis.

Hypertension is the most common comorbidity (28.73%), with the highest risk of unfavorable evolution, followed by diabetes (6.89%). In hospitalized patients, the most frequent comorbidities are hypertension and diabetes (33.33%), hypertension and stroke (9.19%), or hypertension, diabetes mellitus, and chronic kidney disease (5.75%) [21].

Acute stroke was diagnosed in 22.47% of admitted patients [22].

Treatment included interventional procedures, like mechanical thrombectomy for 2 patients with acute stroke, or coronary angioplasty, for 1 patient with STEMI.

The high percentage of deaths among patients who presented with post-COVID 19 symptoms and required hospitalization (29.88%) shows the severity of the complications of COVID-19.

The hospitalized patients without prior medical history (18.69% - 20 patients) are apparently few, but 25% of them (5 patients) died. It is therefore important to monitor the evolution of post-COVID-19 patients without prior comorbidities.

The limitations of the study are the small number of presentations, the study being conducted in a single emergency department, and a lack of data related to the vaccination status of patients (vaccination began in Romania at the end of December 2020).

CONCLUSIONS

The overcrowding of emergency departments and hospitals caused by post-COVID-19 complications becomes a real logistic problem in the context of the currently ongoing SARS-CoV2 pandemic. It appears from the study that late presented patients have unfavorable evolution, with significant mortality and prolonged hospitalization. Some patients died after just 1-3 days of hospitalization.

The importance of the study is great, data being collected from the biggest emergency department in Romania, with the highest number of presentations. The high number of hospitalization days has multiple implications, both for the patients and the medical personnel. The results of the study point out the frequency and severity of post-COVID-19 pathology.

Prompt intervention, targeting cases investigated clinically and radiologically in an outpatient setting, could go the relief of emergency departments overcrowding and a decrease in the rate of hospitalization, and implicitly a decrease in morbidity and mortality, with positive effects on each patient's health, and also in their familial and socio-economic circumstances.

Alteration of levels of thyroid hormones in acute ischemic stroke and its correlation with severity and functional outcome

Brinder M.S. Lamba[1], Shalini Sharma[1], Pulin Gupta[1]

Abstract: *Introduction – With increasing life expectancy and changing trends in diseases, lifestyle diseases come forward and become a major concern. Ischemic stroke is an emerging public health issue leading to significant morbidity and mortality. To improvise positive outcome in acute ischemic stroke (AIS) and optimizing healthcare resources, accurate and timed prognostication of functional outcome is important. Various studies implied derangement of Hypothalamo-pituitary-thyroid (HPT) axis in AIS, thereby advocates neuroprotective properties to these hormones. This is, still, an open field for active research. Thyroid hormones can, therefore, be used as a surrogate tool for outcome predilection in AIS. This prospective observational cohort study aimed to investigate the alteration of levels of thyroid hormones in AIS and simultaneously correlate their levels in assessment of clinical severity and predicting the functional outcome.*

Materials and methods – We had collected data from 60 patients of, radiologically confirmed new cases of AIS who sought medical help within 72 hours of initiation of stroke symptom and had no previous history of thyroid disease.

Blood samples for thyroid function test [TSH, FreeT3 (FT3), and FreeT4 (FT4)] were collected within 24 hours after admission and subsequently at 7th and 30th day of discharge .On admission neurological clinical severity was assessed by using National Institute of Health Stroke Scale (NIHSS). Functional outcome was assessed by Modified Rankin Scale (mRS) at 7th and 30th day of discharge.

Result – Out of 60 AIS patients, 40 were having Non thyroidal illness Syndrome (NTIS). Low T3 was most common NTIS observed. Negative correlation was observed between FT3 levels and on admission NIHSS score and mRS score on follow up.

Conclusion – This study thereby concludes that low T3 levels were associated with clinical severity and poor functional outcome in AIS.

Keywords: *stroke, thyroid profile, correlation, NIHSS, mRS, NTIS*

INTRODUCTION

Stroke, described by the WHO, as the clinical syndrome of rapid onset of focal (or global, in SAH) neurological deficit, persisting more than 24 hrs or leading to death with no apparent cause other than a vascular one. [1]

It is an emerging health problem all over the world. Worldwide every year, 15 million people suffer a stroke. It is the fourth most common cause of death behind the disease of heart, cancer and chronic lower respiratory disease [2]. Globally, stroke is the second leading cause of death above the age of 60 years [3].

After dementia, CVA is the second chief cause of disability. Disability comprise of deprivation of speech and /or vision, confusion and paralysis [3].

Burden of stroke is increasing, which can be, due to

bmsinghlamba@yahoo.com

increasing longevity, smoking, changing habits &lifestyles and type A personality. Beside these, other known risk factors include hypertension, obesity, diabetes mellitus and metabolic syndrome.

In comparison to developed countries, where the incidence of stroke has been decreased or reached a plateau, burden of stroke has been increasing in developing countries [3, 4, 5]. India, like other developing countries, is in the midst of epidemic of stroke.

In rural areas, the estimated adjusted stroke prevalence rate range 84-262/ 100,000 and 334-424/100,000 in urban areas. The incidence rate is 119-145/100,000 based on recent population based studies. [6] In India, nearly one fifth of patients with first ever stroke admitted to hospital is estimated to be of age 40 years or less [7]. Globally, a third of all strokes occur in 20-64 year age group [8].

Stroke can be classified into ischemic and hemorrhagic type. The Indian Collaborative Acute Stroke Study (ICASS) reported that up to 80% stroke were of the ischemic type [9]. The ICMR has advocated tobacco use, diabetes mellitus, hypertension and low concentration of hemoglobin as main risk factors for ischemic CVA [10].

Review of the literature reveals a significant derangement in thyroid hormones in patients with critical illness, specifically during the acute phase [11]. Euthyroid Sick Syndrome or Non Thyroidal Illness Syndrome (NTIS) is a condition in which derangement of thyroid hormones occurs in association with severity of disease and stress like surgeries [12] The most common pattern found under NTIS is low T3 level with normal level of T4 and TSH [13,14].

In acute ischemic stroke (AIS), HPT axis are significantly deranged. Various studies advocate low T3 levels as an indicator of poor prognosis in AIS [15, 16]. A reduction of serum T3 without elevation of TSH is associated with severity and worse clinical outcome in stroke [15, 17, 18]. Whether the prognosis is direr in AIS patients than those with the same disease but without the low T3 syndrome remain unknown. In AIS, implication of thyroid hormones is hence, controversial.

Low T4 syndrome, a condition found in severe illness, in which T3 and T4 levels are reduced while TSH level does not show expected pituitary thyroid axis reactivity [13, 14]

After acute stroke, better survivals were reported even when the cut-off point used was the median T3 levels [15], showing that lower T3, even it is in the normal range, may be associated with poorer prognosis. However, the association was not confirmed by other studies [19-21]. Therefore, it is not clear if, in ischemic CVA, lower T3 levels, especially within the normal range, on hospital admission provide worthy prognosticative information. A better understanding of this issue can be used for risk stratification in AIS and hence better healthcare resource utilization.

The basic aim of our study was to find out whether there occurs any alteration in thyroid hormone levels in AIS and also to correlate their levels in assessment of stroke severity and functional outcome as evaluated by using NIHSS and modified Rankin scale (mRS) respectively.

MATERIALS AND METHODS

This study was performed at the Department of Medicine at PGIMER (Post Graduate Institute of Medical Education and Research), Dr RML Hospital, New Delhi from November 2016 to March 2018. It was a prospective observational study in which a cohort of 60 patients of AIS was admitted and followed up at 7th and 30th day after discharge.

Inclusion criteria

Any patient of age 18 years or older & with no previous history of thyroid hormone abnormality, with first ever radiologically confirmed ischemic CVA presented within 72 hours of onset of stroke symptoms.

Exclusion criteria

1. Patients with known thyroid disease or biochemically defined overt thyroid disease,
2. Patients with transient ischemic attack, or past history of stroke,
3. Those using medications that can affect thyroid functions,
4. Those with cancer, severe renal or liver failure, inflammatory or infectious diseases and hematological diseases.

The enrolment of patients was done after informed consent. All the issues, including ethical issues of the study had been reviewed by the Institutional Review Board and approved.

The patient was first evaluated clinically which include a detailed history and examination.

Baseline characteristics, include demographic data such as age, gender, and concurrent diseases, thyroid disorder related medication use, risk factors of stroke, such as a history of diabetes mellitus, coronary artery disease hypertension, smoking and TIA.

Acute ischemic CVA was confirmed by using radiological modality NCCT head /CECT head/MRI brain was used.

On admission, stroke severity was assessed by using NIHS scale and was divided into 3 categories:-

- Mild NIHSS score <8
- Moderate NIHSS score 8-14
- Severe NIHSS score ≥ 14

Blood samples for assessment of the thyroid profile was drawn within the first 24hrs of presentation and then subsequently during follow up at 7th day and 30th day after discharge.

FT3, FT4 and TSH was measured by using chemiluminescent micro particle immunoassay.

Normal range in our laboratory is

- TSH 0.5-5.0 U/ml
- Free T3 (FT3) 2.0-4.4 pg/dl
- Free T4 (FT4) 0.7-2.0 ng/dl

On the basis of thyroid profile, the patients were divided into five categories:

1. NTIS was diagnosed as a low FT3, low or normal FT4, and low or normal TSH. Low T3 syndrome was defined as low FT3 levels with normal TSH and FT4 levels. [19, 22, 23, 28]

2. Euthyroid was diagnosed as normal FT3, FT4, and TSH. [19, 22, 23]

3. Subclinical hypothyroid was diagnosed as normal FT3, normal FT4, and high TSH. [24, 25, 26, 27, 29]

4. Hyperthyroid was diagnosed as low TSH with or without high FT4 and FT3 [22, 30, 31]

5. Hypothyroid was diagnosed as high TSH with low FT4 and normal FT3. [23, 30, 31]

Functional outcome was evaluated by using the Modified Rankin Scale (mRS) at the first follow up clinic visit at 7th day and subsequently 30th day after discharge. The mRS [32, 33, 34] is a scale to determine the disability after stroke. It has a score of 0-6, with 0 referring to no limitations or symptoms, 5 being severe disability requiring constant care and 6 being dead

On the basis of this scale, patients were divided into 2 outcome groups:

- Poor functional outcome (mRS > 2)
- Good functional outcome (mRS ≤ 2)

Data was analysed by using SPSS version 21.0 Qualitative & categorical or nominal variables were expressed as numbers (percent) or proportion. Quantitative & continuous or ordinal variables were expressed as medians or mean ± standard deviation (SD) Association and comparison of two categorical variables was done by using Chi square. The association between thyroid hormone levels and stroke severity and functional outcome was evaluated by Pearson correlation. The chi square and independent sample t test were used to compare respective categorical and continuous variables between different outcome groups. Variables with significant difference between different outcome groups were included in multiple logistic regression analysis. The criterion of statistical significance was set at p value < 0.05.

RESULTS

The mean age of the study population was 63.75 ±11.755 SD years with maximum age reported was 87 years and the minimum age was 38 years (Figure 1). Out of 60 study subjects 14 were female and 46 were male (Figure 2), suggesting ischemic stroke was more frequent in male (76.7%) as compared to female (23.3%) and male to female ratio was 3.28:1.

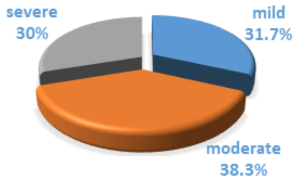
The incidence of stroke increases with presence of risk factors. Common vascular risk factors, as shown in Table 1, included in the study were hypertension (n=40, 66.7%), diabetes (n=23, 38.3%), smoking (n=38, 63.3%) and dyslipidaemia (n=17, 28.3%).

Figure 3.



At admission, 19 patients (31.7%) had mild, 23 (38.3%) had moderate, whereas 18 (30%) had a severe stroke on NIHS scale (Figure 3). There was no statistical significant difference found between NIHSS score and age, gender, vascular risk factors for stroke studied (p value >0.05).

*** Correlation is significant at the 0.01 level (2-tailed).*
FT3_P: free T3 levels on presentation /admission

In order to study the impact of T3 levels of severity & outcome of stroke in our study, we divided cohort of 60 patients into two groups – low T3 and normal T3 group and also analyze the distribution of risk factors among them (Table 2). No significant difference observed between age, gender & vascular risk factors between these two groups.

There were significant negative correlations between free T3 (FT3) levels and NIHSS scores on admission (n=60, r= -0.712, r2=0.507, p=0.000, 99%CI, Figure 6, Table 3) among all patients. This implies, after acute stroke, that the lower FT3 values are, the worse neurological impairment will be.

NIHSS Score was negatively correlated with TSH on admission as well as 7th and 30th day of discharge (Table 4 – correlation is significant at the 0.01 level 2-tailed). NIHSS Scores were shown a negative correlation with FT4 values only on follow up. Although the strength of the correlation was not as stronger as it was with FT3 levels.

ASSESSMENT OF FUNCTIONAL OUTCOME

Final outcomes were evaluated at 7th and 30th day of discharge and the mRS score so obtained was compared with on admission NIHSS Score as well as thyroid hormone levels measured concurrently.

Out of 60 patients, 36 patients (60%) had a poor functional outcome (mRS>2) at 7th day of discharge in comparison to 29 patients (48.3%) who still had a poor functional outcome at 30th day of discharge.

No mortality either in hospital or hospice was observed on first following up clinic visit. However, on second follow up clinic visit, 4 patients, among those with poor functional outcome had mRS Score 6 (dead) constituting 13.7 % of patients with mRS score>2. Retrospective analysis of these patients revealed that they had a severe stroke on NIHS scale. Analysis of thyroid hormone pattern on admission and at 7th day of discharge were suggesting that they belong to the low T3 syndrome. They had very low levels of free T3. TSH and free T4 levels were also low. These mortalities thereby emphasize severe derangement of hypothalamo-pituitary-thyroid axis.

Univariate analysis showed that mRS scores at first and second follow up visit, were not associated with age, gender and vascular risk factors like hypertension, smoking, diabetes & dyslipidaemia (p>0.05, Table 5).

Table 5: Demographic and vascular risk factors according to outcome at 7th & 30th day of discharge

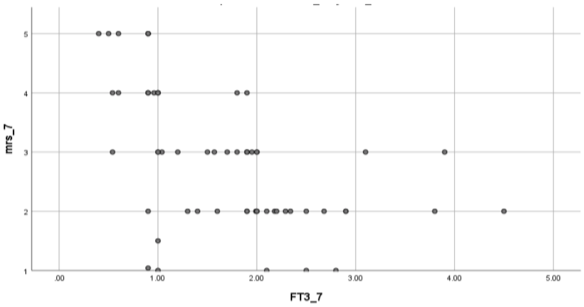
FT3	2.20±0.84	1.33±.73	2.13±0.86	1.20±0.61	<0.05
FT4	1.56±0.65	1.47±0.64	1.60±0.72	1.42±0.45	<0.05
Thyroid hormone levels at 30th day of discharge					
TSH	3.17±2.05	2.66±1.47	2.42±1.36	2.40±1.23	<0.05
FT3	2.30±0.81	1.42±0.82	3.31±2.01	1.24±0.71	<0.05
FT4	1.58±0.61	1.35±0.54	2.30±0.81	1.24±0.43	<0.05

Patients with poor functional outcome were having high baseline & median NIHSS Score. The majority of patients with poor outcome had moderate to severe score on NIHS Scale (p value <0.05, Table 6). Free T3 levels were significantly lower in them during first as well second follow up visit (p value <0.05, Table 6).

Figure 7. Scatter plot between FT3 values and mRS_7 scores at 7th day of discharge



These findings, consistent with the findings reported by Xu and his colleagues [21], which is due to the fact that in patients with poor functional outcome there might be decreased peripheral conversion of FT4 to FT3 which lead to low levels of FT3.

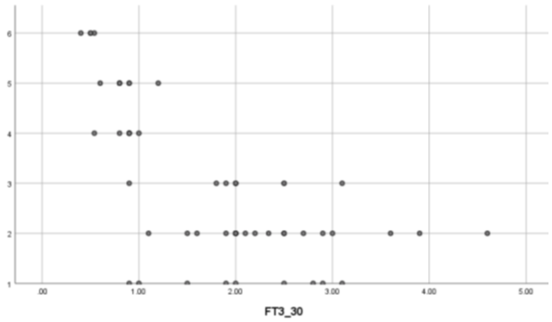
mRS_30: mRS score at 30th day of discharge

On 2nd follow up clinic visit, similar trends of negative correlation was observed between mRS score and free T3 levels (Figure 8, Table 9).

This implies that AIS patients with the low T3 syndrome tend to have poor outcome at follow up. From Table 8, it was inferred that at first follow up visit, no statistically significant correlation found between mRS score and FT4 levels (neither an admission nor at 7th day of discharge). There were a statistically significant negative correlation between TSH levels (on admission, at 7th and 30th day of discharge) and mRS score at 30th day of discharge (p value <0.05, Table 9). No relation was seen between FT4 levels (on admission, & at 7th day of discharge) and mRS score at 2nd follow up visit (p value >0.05, Table 9). But a negative relationship seen between the two at 30th day of discharge (r = -0.387, CI 95%, p value <0.05, Table 9).

Figure 8. Scatter plot graph between FT3_30 values and mRS_30 scores at 30th day of discharge.



This findings can be explained by the fact that even with the severity of stroke, levels of T3 decrease immediately, but it requires some time for T4 levels to show changes in their levels.

On multiple logistic regression analysis (Table 10), lower FT3 concentration (odds ratio OR=1.166, 95%CI, p value <0.05) remained independently related to poor outcomes.

Table 10: Multiple logistic regression analysis

	detoriation	8	0	8	
Total		45	15	60	

ΔmRS = change in functional outcome (mRS_30 score - mRS_7 score)
Δthyroid pattern = change in thyroid pattern

Figure 9. Thyroid hormones pattern observed at various time interval in this study

	LOW T3	EUTHYROID	SCH	HYPERTHYROID	HYPOTHYROID
■ ON ADMISSION	40	8	4	3	5
■ AT 7TH DAY DISCHARGE	36	12	4	3	5
■ AT 30TH DAY DISCHARGE	23	23	4	1	5

In addition to the FT3, the only other variables independently associated with poor functional outcome were NIHSS score (OR=0.641, 95% CI, p value <0.05) and TSH levels (OR=0.936, 95%CI, p value <0.05).

Of 40 patients with the low T3 syndrome, 13 patients became euthyroid on follow up (Figures 4 & 9, Table 11). This can be explained by the fact that during disease recovery, thyroid hormones and TSH concentrations return to normal [35]. This emphasize the need to follow up of such patients to confirm suspected cases of sick euthyroid. Similarly, on follow up, a very small percentage had shown improvement in their functional outcome. However, this finding was not statistically significant (p>0.05).

DISCUSSIONS

Conduction of this study was done with an objective to decipher the relationship between thyroid hormone levels and functional outcome in AIS. Observations recorded were similar to studies conducted by Alvezaki et al [17] and Zhang et al [19]. In hospitalized patients, especially in ICUs, the most common type of NTIS seen is low T3 [36, 37]. In ICH from either trauma or hemorrhagic CVA, low T3 has been reported [38, 39]. The present study showed thyroid hormones derangement in AIS and most common type of it was NTIS/low T3 syndrome.

An inverse relationship between T3 levels and NIHSS score was observed in our study. To follow up, patients with poor functional outcomes were found to have low free T3 levels. Thus, an inverse relationship observed between FT3 value and NIHSS score as well as mRS score, thereby strengthening its predictive role in estimating the severity and functional outcome in AIS.

The degree of decrease in T3 levels is related to worse neurological impairment. Thus, monitoring levels of FT3 could potentially be an easy, quick and surrogate marker in the future if other studies confirmed it further. The observations and findings delineated in the present study were similar to studies done by Alvezaki et al [17] which stated that low T3 is a possible independent predictor of stroke outcome.

In severe illness, T3 levels would decline to spare energy, considering it as an adaptive response to stressful conditions. [40-44].

Similar to other systemic severe diseases, a decline in serum T3 with no increment in TSH levels seem to be related to stroke severity and poor clinical outcome [17, 20, 45-47].

Possible mechanisms include the following:

(1) Change in the peripheral metabolism of thyroid hormones due to alterations in enzyme activity involved in peripheral T4 to T3 conversion, [42, 48]

(2) Involvement of pro-inflammatory cytokine action, [49]

(3) A disturbed shift in thyroid hormone distribution or change in binding proteins, [41, 49, 50]

(4) In severe illness, excessive glucocorticoids release, which lead to inhibition of hypothalamic-pituitary- thyroid axis activities and T4 to T3 conversion. [51]

Similar to various studies conducted in ICUs, AIS patients with low T3 or combination with low T3 and T4 found to have a worse prognosis. [15, 43, 48, 52-54]

Interestingly, studies showed that derangement in T3 levels is not related with regional distribution of stroke (anterior vs posterior circulation). This change in thyroid hormone levels can, therefore, be due to disturbance in their metabolism instead of any structural defect induced due to abnormality in blood supply to hypothalamic-pituitary-thyroid axis. [19, 23]

A significant negative correlation observed between NIHSS score and TSH (p value < 0.05) on admission and on follow up. On admission, no correlation was observed between NIHSS score and free T4, however, negative correlations observed between them only to follow up. Unlike, NIHSS score and FT3 levels, strength of association between NIHSS score and TSH & T4 levels were not strong.

After CVA onset, within hours, the decline in serum T3 levels and degree of alteration in its levels is associated with the severity of stroke.[48 ,55-57] In severely ill patients, levels of T4 also decrease [55, 57]. A drop in FT4 levels represents a continuum of the NTIS spectrum in which as illness progresses in its severity, levels of FT4 would decrease. Therefore, low FT4 levels also correlated with bad prognosis.

However, no relationship of NIHSS score with FT4 levels on admission can be explained by the fact that with the severity of stroke there occurs decrease in the peripheral conversion of T4 to T3 as a result of which T3 levels would decrease but T4 levels would either normal or increases. Similar findings were reported by Xu and his colleagues in their study [21] that T4 levels were found to be increased in patients with higher scores on NIHS scale and hence those with poorer prognosis can have higher or normal T4 levels.

On univariate analysis, during follow up, no relationship was observed between mRS score and baseline parameters, i.e. age, gender and vascular risk factors. It was observed that AIS patients with high moors scores had low levels of free T3 and also had a high NIHSS score, both baseline and median. These findings, consistent with the findings reported by Xu and his colleagues [21], which is due to the fact that in patients with poor functional outcome there might be decreased peripheral conversion of FT4 to FT3 which lead to low levels of FT3.

At first follow up clinic visit, only other thyroid parameters with which mRS score can be correlated was TSH. Similarly, on 2nd follow up visit, mRS score was negatively correlated with TSH levels. A negative correlation was observed between free T4 and 2nd follow up visit mRS score only at 30th day of discharge. To sum up, apart from free T3, TSH levels would be next important parameter to determine functional outcome in AIS. However, free T4 would not show any significant change in its level immediately, but ultimately its levels also decrease in those with severe stroke and poor outcome which would be observed only on follow up.

In the present study, no significant difference observed between age, gender and vascular risk factors among AIS patients with low T3 and those with normal T3 levels. Zhang et al [19] study, however, showed that low T3 group patients were slightly but not significantly older. Alvezaki et al [17] study showed that patients under low T3 group were significantly older. In elderly, baseline thyroid function is usually at the lower side and when stressful events like stroke occurs, they tended not to compensate fully. This was the explanation offered by his study.

Except low T3 subgroup, none of the other subgroups had shown any mortality. In this subgroup on follow up, 4 patients (10%) were expired. Retrospective analysis of these patients showed that they had a severe stroke on NIHS Scale and had very low levels of FT3.TSH and free T4 levels were also at the lower range. These mortalities emphasize a severe derangement in HPT axis. These findings were consistent with studies which advocate that long term survival is poor in patients with the low T3 syndrome and emphasized that ischemic stroke patients with the low T3 syndrome were at higher risk of poor outcome on follow-up that was arranged from 2 to 4 weeks after ischemic CVA and 1-year survival was remarkably worse in CVA patients with the low T3 syndrome. The outcomes were supported by other studies. [17, 19]

We, in the end, conclude that there is alteration in levels of thyroid hormones in AIS and low T3 levels are predictive of severity and functional outcome in these patients. However, the understanding of pituitary-thyroid axis, factors controlling action of thyroid hormone at the cellular level and explanation of different arrays of thyroid function tests may be considered cardinal in the management of ischemic CVA.

CONCLUSIONS

In acute ischemic stroke, there is the major impact of thyroid dysfunction. In such patients non thyroidal illness (NTIS) is not uncommon and reflect the increase in physical stress associated with the insult. The present study showed that severity of initial (functional) impairment measured by an NIH Stroke scale on admission, and free T3 & TSH levels had an independent predictive role in determining the functional outcome.

LIMITATIONS OF THE STUDY

Although the research was prepared carefully, there were some inevitable limitations such as small size of the sample, shortfall of long term follow up, selection biases, etc. Due to time constraint, this study was conducted on a small sample size, but it is advised to conduct it on large population so that better results and better comprehension of subjects can be made.

The work was carried out in Post Graduate Institute of Medical Education and Research (PGIMER), Dr. R.M.L. Hospital, New Delhi – 110001. No financial assistance or funding was taken from any source.

The Authors thank the Director and Dean of Post Graduate Institute of Medical Education and Research (PGIMER), Dr. R.M.L. Hospital New Delhi for granting permission to conduct the work.

A marketing perspective on the efficient strategies in Romanian family medicine

Traian Soare[1], Ciprian Ianovici[1], Iuliana R. Gheorghe[1], Victor L. Purcărea[1], Cristina M. Soare[1]

Abstract: *Family Medicine has always been regarded as an interdisciplinary specialty, but lately, in most Eastern-European countries, such as Romania, it has been supported by many laws and regulations. The outcome of this prolific background has brought both advantages and disadvantages. Some advantages relate to a sustainable structure, and, at the same time, Family Medicine has been recognized as being the gate-keeper in almost any health care system. Further, due to the privatization of most family practice offices, in Romania, appeared a modern organizational approach, in the shape of a consortium of family physician practices. Some family physicians consider providing their services in a private office as a benefit, but for others the freedom and autonomy to become responsible of their own practice is considered to be a drawback because, apart from the clinical activity, many family physicians have to deal with managerial and marketing issues. In Romania, a consortium of family practice offices has to overcome a very competitive environment and some Marketing specific trends. The aim of this paper is to investigate the usefulness of marketing strategies in the Romanian family physician practice.*

Keywords: *family medicine, family physician, primary care, marketing, word-of-mouth, WOM*

INTRODUCTION

From its beginnings, the Family Medicine specialty has raised considerable discussion and debates regarding its scope and borders from an interdisciplinary perspective [1-3]. Since the Alma Ata conference in 1978 [4] and the World Health Organization's program, called "Health for All" [5], the importance of efficient primary care has been recognized as being the foundation of health systems in many parts of the world [6]. However, today Family medicine continues to face an unclear identity, as the scope of the practice is not well-defined and its consequences may trigger issues that relate to medical malpractice, healthcare coverage and insurance reimbursement [7].

In Central and Eastern European countries, health care systems are very much specialist and hospital oriented but the importance of family care still remains in the background, and it is not fully supported by focused strategies [8]. In the pandemic context, most of these countries have undergone rapid political changes and challenges that led to the necessity of developing and supporting the activities of the Family Medicine.

Since the collapse of the communist regime, the Eastern-European countries have made a radical transformation in the family care practice [9]. Once, under the umbrella of the impersonal polyclinic services and the purview of the law, the family practice offices have been privatized and are often managed by the family physicians themselves. Moreover, this privatization triggered an emergent decentralized primary care sector, which lacks the team-based care approach.

Although in most of this region many countries still struggle for the on-going acceptance and recognition, in Romania, there has been an upsurge of laws supporting the family practice activity and discipline-specific associations that recognize its fundamental position in the health care system. For instance, solo family practices have mostly disappeared in the Romanian urban areas, being replaced by a modern perspective, namely, building consortium of family physician practices [10]. In 2019, in Romania, there were 11,682 family physicians, who provided around 30,720,485 receipts [11].

raluca.gheorghe@umfcd.ro

Further, the organizations that promote and support the modern Family Medicine are: The Romanian Society of Family Medicine/General Medicine, The Family Medicine Commission of the Medical College of Physicians and the National Centre for Studies in Family Medicine. The most important organization is the Romanian Society of Family Medicine/General Medicine because it is the biggest association of family physicians and has a long tradition in supporting the development of Family Medicine, as a distinct specialty in Romania [12].

The self-employed status of a family physician has brought with it a wide range of other responsibilities besides the clinical activity. The family physician has to take responsibility for the equipment and supporting staff as well as for the management of the practice. In fact, family physicians had to learn about management and marketing strategies in order to develop and implement a modern concept of their practice and offer a competitive advantage.

The aim of this paper is to investigate the usefulness of marketing strategies in the Romanian family physician practice

THE PARTICULARITIES OF FAMILY MEDICINE IN ROMANIA

Family physicians are the core stakeholders in delivering any health policy by providing primary care services, and the first contact of patients with the health system [13]. Although, the World Health Organization has defined their role in the primary health practice and their importance is widely accepted, there may be registered some differences between countries [14]. Specifically for the Family Medicine, the scientific literature revealed that the most often encountered differences relate to the incentives, practice information capacity, access, the use of quality indicators, staff and patient safety and the number of allowed patients in a portfolio of a family physician [15].

In Romania, the family physician is a person responsible with the provision of comprehensive and continuing care to every individual in need, regardless of age, gender and illness, but who is under his supervision [16]. Broadly, family physicians integrate in their professional practice activities that focus on the health and prevention measures as well as activities that concentrate on the provision of cure, care or palliation. A family physician provides these services either directly or through the services of other specialists, according to the health needs and the resources available within a community.

The particularities of Family Medicine in Romania are [16]:

- The family practice office is normally the point of first medical contact within the health care system, which provides open and unlimited access to its users, dealing with all health problems regardless of the age, sex, or any other characteristic of an individual;

- The family physician makes efficient use of health care resources through coordinated care, working with other professionals in the primary care setting, having an advocacy role for the patient in need;

- The family physician has a person-centred approach, orientated towards both the individual, his/her family, and their community;

- The family physician has a unique consultation process, which should establish a long-term relationship with the patients, through effective communication strategies;

- The family physician is responsible for the provision of longitudinal continuity of care as determined by the needs of the patient;

- The family physician has a specific decision making process determined by the prevalence and incidence of illness in the community;

- The family physician manages simultaneously both acute and chronic health problems of patients;

- The family physician manages illnesses at early stages of evolution;

- The family physician promotes health and well-being ideas for individuals through appropriate and effective interventions.

- The family physician deals with health problems in their physical, psychological, social, cultural and existential dimensions.

According to the Primary Health Care Activity Monitor for Europe [17], Romania has one of the strongest primary care structures, along with Denmark, Finland, Italy, Portugal and United Kingdom, but the critical issues in a family physician activity resumes to buying modern equipment, competence involvement and using appropriate appointment systems [18].

Despite having an interdisciplinary approach, family physicians have identified the following challenges in providing their specialty [18]:

- Less attractive – Due to the economical and managerial freedom, most family physicians no longer find this medical specialty attractive. The former enjoyment of working on a private basis has been replaced by disappointment because the workload has not been reduced, especially in the pandemic context.

- Constant need to buy modern equipment – In order to deliver quality health care services, family physicians need to keep track of the latest equipment and, as the patient becomes more empowered with information, they need to understand that the patients' needs have been raised as well. In Romania, some family physician offices have been equipped with computers and printers, electrocardiographs, spirometers, CT scanners and even office-based laboratory tests.

- Raise the continuing professional development credits – The family physician's activity is influenced by the quality improvement initiatives of their practice in the shape of a constant participation to conferences and other specific events or publish certain articles, books and other materials that would help them build their knowledge and learn about the latest medical information. Yearly, getting the credits imposed by the laws, leads to a re-certification of the family physician.

- Impairment in accessing the academic field – Although the academic positions opened for family practitioners have improved significantly, there are a few issues that need to be addressed, as for instance the salience of Family Medicine as a discipline and its connections with other medical specialties [19].

Moreover, the indicators specific to Family Medicine relate to health care quality, and the elements that need to be addressed are linked to continuity, coordination, comprehensiveness of care and community orientation. [20] Continuity is described by informational, relational and management activities, while the coordination is reflected in the organization and the monitoring of the services delivery. In Romania, the family physician's continuity and coordination are connected to the medical records and electronic medical records and with the collaboration with other specialists. The comprehensiveness is reflected in the scope of the practice and in the range of services provided, whereas the community orientation is important to be ensured for the sustainability of the health care system. In Romania, both the comprehensiveness and the community orientation are extremely low because the family physician provides the basic services or ancillary services, with a specific interest, for ultrasound or gynaecology related services, and the community orientation is non-existent because family physicians are too busy with their clinical activities in order to have other voluntary activities.

All four elements reduce to the doctor-patient relationship, this being the core characteristic of the Family Medicine [21]. If the practice gets influenced in a negative direction by the doctor-patient relationship, than there would be significant implications at the image level and the patients' desirability to continue going to the family physician. In addition, since 1999, when the family physician's form of payment switched from a salary paid by the system to a yearly contract based model, the family physicians became the gate keepers of the health system but was also introduced the freedom of patient choice of a family physician. Therefore, family physicians have to catch the attention of patients through different strategies and build their portfolios as well as offer a competitive advantage. In fact, family physicians had to implement efficient marketing strategies in order to survive on a market.

CURRENT CHALLENGES OF FAMILY MEDICINE IN ROMANIA

Health care is a field in a permanent and constant evolution, being filled with a wide range of opportunities that should stimulate creativity and enthusiasm of the specialists in the field. Still, health care services are not like other services because they are unwanted, and this may be considered highly troublesome by patients and, at the same time, critically important for their well-being [22]. Actually, health care services have always been archetypal in nature because consumers lack the technical knowledge to understand it, and have to rely on credence qualities [23]. Consequently, entropy of information is formed and consumers will assess the quality of the provided health care services based on their perceptions and not on their real experiences. If we take into consideration the pressure which consumers face in making health care decisions, we may conclude that patients confront with a challenging lack of accessible and medically verified information that would, eventually, help them in rationally think about the benefits and drawbacks of the medical procedures [24]. Moreover, frequently, the desires and the needs of health care consumers come in conflict, resulting in their reluctance to play the role of co-producers [25], but physicians motivate them to assume their part in the health care process by using ethics, compassion, empathy, and solidarity [26].

Doyle [27] mentioned that patient experience consists of two aspects: rational and functional. The rational aspect focuses on the 'interpersonal aspects of care', such as the physicians' ability to treat patients with respect and compassion, to empower patients with information in order to prevent other illnesses, as well as, to highly engage patients and their family members in the decision-making process, whereas the functional aspect relates to the patient's basic expectations about the health care service, which includes elements such as the effectiveness and efficiency of health care delivery and the cleanliness and safety of the health care background.

Due to the emergence of technology, patient emancipation or patient empowerment became the most substantial and visible trend [28], prior to sickness in the shape of prevention methods or upon its primary form, in the shape of diagnosis, treatment, and during the treatment period, shaped by the degree of compliance. This trend has fundamentally changed not only the doctor–patient relationships, but also the relationships established between doctor–society– patient, as a whole. As such, the passive patient has changed and became involved and proactive in designing the process of care and taking decisions. Also, this trend triggered several changes in the providers' perspectives that emphasized the necessity for greater authority and involvement in care from the regulatory and funding bodies as well as from the stakeholders, who had to change their behaviors, through financial, structural, and organizational mechanisms. These strategies had to significantly rely on patient expectations, and basically, to improve patient support by using personalized communication about preventive advice and reorientation based on consumption analyses, and, implement Marketing instruments and principles [29]. Marketing plays an important role in helping health care professionals to create, communicate, and provide value to their target market- the health care consumers- by building a sustainable relationship [30].

Although many experts have considered the emergence of Health Marketing as a distinct field, few specialists have provided clear and integrative definitions [31].

Over the past decade, some market specific trends contributed to integrating Marketing in the health care field. These trends are the following [32]:

- From a mass-marketing approach to a more specific approach;
- From "one measure for all" to personalization;
- From the emphasis on a health episode to a long-lasting relationship;
- From low-technology market to high-technology market.

From a Marketing perspective, the process of providing health care services must be conducted according to the patient requirements, because these activities are designed to satisfy their needs and wants. The main argument in adopting a Marketing perspective in health care services steams from the objectives of the health care systems around the world, namely, assessing a balance of financial-territorial resource allocation and the control of costs, reducing the inadequate technology employment and introducing modern managerial methods [33]. Further, a high performing health system is characterized by the following features: accessibility, pertinence toward the needs, equity, chance of selection, efficacy and efficiency, and large scale social accessibility [30]. So, everyone has the right to non- discriminant medical attendance and health care organizations should satisfy the needs of the health care consumers in a timely manner. In addition, along with these challenges, competition in the health care market has increased in certain medical specialties, as in the case of Family Medicine.

In Family Medicine, Marketing strategies should be tailored differently for patients and families, communities, other physicians with whom they work with and other categories of medical personnel, in the shape of promotion strategies. As such, promotion strategies include a carefully designed set of activities intended to induce change with the help of a message.

Frequently, promotion strategies concentrate on various elements such as specific communication objectives for each target audience, guidelines for designing attention-catching and effective messages, and designing appropriate communication channels [34]. However, promotion is considered discreditable among the medical profession because there is a strong social norm against advertising in the health care field [35]. Although, consumers typically receive most of the information about health care services from Mass-Media, in fact, the most important information comes from recommendations from family or peers, which take the form of word-of-mouth.

WOM is the most powerful form of Marketing that can be easily used by physicians [36], and that may influence consumer expectations [37], pre-usage attitudes [38] and post-usage perceptions of a service [39]. In Family Medicine, WOM may be useful for consumer decision-making because it is quick, convenient, cost-free and it saves time and effort. Actually, the two categories of sources have complementary functions in Family Medicine, namely, Mass-Media informs and builds awareness, whereas the personal sources raise the potential evaluation process in looking for information. In the pandemic context, many family physicians made use of the WOM in the online environment by keeping up-to-date informative blogs and articles published on Social Media. Hence, the main benefits of implementing promotion strategies in a Family Medicine are the following:

- to improve the competitive advantage;
- to increase visibility;
- to create a positive reputation among patients;

- to monitor the expectations of consumers;
- to build a brand.

eWOM generated by patients is based on their referrals, and these recommendations, in their turn, are the outcomes of physician-patient interactions or experiences [40]. For instance, negative eWOM in health care services is expressed in the shape of online messages, in which are embedded emotions, such as anger [40]. In order to avoid the spread of negative eWOM, family physicians may elaborate or contribute to the design of a patient journey.

Patient journey maps [41] are used to measure patient experience after an interaction with a physician from the patient's perspective. The aim of a patient journey map is to capture the key elements of a journey, consisting of patient persona, medical timeline, medical pathway, relationships between elements and rules of getting from the starting point to the ending point. Going further with an in-depth analysis, the patient persona offers details about the user group and their emotional, physical and technological journey, and each interaction with the physician should be divided into tasks.

CONCLUSION

Health Care Marketing strategies have proved to be useful in Family Medicine. Marketing strategies may focus on the referral or recommendation solutions generated by patients, known as word-of-mouth. The outcome of WOM is to build a positive reputation and to attract more patients for a portfolio of a family physician. In order to avoid negative WOM, family physicians should design a patient journey map.

Analysis of COVID-19-related psychiatric disorders – clinical manifestations and therapeutic considerations

Octavian Vasiliu[1], Andrei G. Mangalagiu[1], Bogdan M. Petrescu[1], Cristian A. Cândea[1], Corina Tudor[1], Daniel Vasile[1]

Abstract: *During the COVID-19 pandemic, neuropsychiatric disorders have been diagnosed both in the acute phase, and in the aftermath of this disease. Inpatients, as well as outpatients recently diagnosed with mild, moderate or severe forms of Coronavirus infection have reported neuropsychiatric manifestations with variable duration, symptoms that could be directly or indirectly related to the viral pathogenic agent. Patients who are recovering from the acute phase of COVID-19 also may exhibit various psychopathological manifestations, during the so-called "post-COVID-19 syndrome" or "long COVID-19 syndrome". Explanations regarding the onset of this type of clinical manifestations and the SARS-CoV-2 infection are extremely diverse, ranging from biological factors (e.g., direct central nervous system viral activity, cerebral hypo-oxygenation, high level of inflammatory response) to psycho-social stressors (e.g., isolation, fear of death, anxiety related to possible somatic complications or sequelae). Objectives: The primary objective of this article was to analyze psychiatric manifestations in patients with acute COVID-19 disease and in patients during post-COVID-19 phase. The secondary objective was to propose a conceptual framework for the evaluation and treatment of these patients. Methods: Patients included in this analysis were screened positive for COVID-19 infection in the last 6 months before their first psychiatric examination. These patients were further evaluated to detect any personal history of psychiatric disorders, somatic comorbidities, or significant concomitant pharmacological treatments. Specific scales for the measurement of symptoms severity and functional impairment were administered in all patients. Results: Five patients were included in this analysis, one during the acute phase of COVID-19 infection, and four patients were evaluated after the complete remission of this disease. Hyperactive delirium, mild neurocognitive disorder, major depressive episode, panic disorder with agoraphobia, or acute psychotic disorder were the main diagnoses in these patients. All patients received adequate treatment and they were monitored using psychological scales until symptoms remission or stabilisation. Conclusions: Psychosocial stressors, neurobiological changes, systemic inflammatory reaction, and individual vulnerability factors may contribute to a diathesis-stress model for psychiatric disorders onset within the acute phase or after the remission of acute manifestations in COVID-19-diagnosed patients.*

Keywords: *COVID-19, long COVID-19 syndrome, psychotic disorders, major depression, neurocognitive disorder, delirium, panic disorder*

INTRODUCTION

Although the primary target cells for SARS-CoV-2 are epithelial cells of the respiratory and gastrointestinal tract, it is believed that the penetration of the virus in the human body are far from being limited to these organs [1,2]. The presence of neurological manifestations, such as headache, anosmia/ageusia, dizziness, seizures, and strokes suggests also the invasion of the central nervous system (CNS) during COVID-19 infection [2,3]. Data derived from both patient and experimental models of β-coronaviruses infection support this hypothesis of CNS involvement, due to their evident neurotropism (SARS- CoV-2, MERS-CoV, HCoV-HKU1, HCoV-NL63, HCoV-OC43, HCoV-229E) [2]. This invasion of the CNS is presumed to occur directly, through peripheral nerves or via systemic blood circulation, but aberrant immune responses and respiratory insufficiency associated with COVID-19 are indirect mechanisms that could also explain neurologic manifestations [3]. However, only few studies have reported the presence of SARS-CoV-2 in cerebrospinal fluid or brain parenchyma [3]. It is speculated that a potential trigger of multi-organ autoimmunity in COVID-19

[1] Carol Davila University Central Emergency Military Hospital, Bucharest, Romania

infection could be the molecular mimicry between SARS-CoV-2 proteins and different human cell antigens, CNS cells included [3,4].

The importance of psychosocial factors in the onset of COVID-19-related psychiatric disorder is significant, starting from social isolation, to negative impact over the financial status or professional performances, lower quality of life, changes in day-to-day functioning etc. [5,6]. All these factors might translate into different psychiatric disorders, including post-traumatic stress disorder, depression, sleep disorders, or isolated neuropsychiatric symptoms [6]. A frequently reported finding is that the pandemic had a significant negative effect over the mental health status in people compared to their average mental health levels during previous years, although this difference is mediated by age, gender, ethnicity and other factors [6]. This observation is supported by an increased prevalence of depression, post-traumatic stress, and sleep disorders in the last years [6,7]. According to a review, symptoms of anxiety and depression (16-28%) and self-reported stress (8%) are common psychological reactions to the COVID-19 pandemic, and they may be associated with disturbed sleep [7]. Both clinical and sub-syndromal mental health problems should be actively investigated, especially in vulnerable populations, as possible reactions to the COVID-19 pandemic. If left untreated, these problems may worsen and lead to long-term complications, with negative, invalidating consequences.

Anxiety and depression spectrum symptoms and disorders in COVID-19 survivors were frequently identified at one month after discharge from hospital in a study (N=402 adults), with rates reaching 28% for post-traumatic stress disorder, 31% for depression, 42% for anxiety, 20% for obsessive-compulsive symptoms, and 40% for insomnia [8]. More than half of the individuals questioned in this study about the existence of psychiatric manifestations or disorders scored in the pathological range in at least one clinical dimension [8]. Patients with psychiatric history showed increased scores on most psychopathological measures, even in the presence of similar baseline level of inflammation [8]. Anxiety and depression scores at follow-up were associated with baseline systemic immune-inflammation index, which evaluates the immune response and systemic inflammation [8].

A study evaluating 841 patients hospitalized with COVID-19 (mean age 66.4 years) showed that 57.4% developed at least one type of neuropsychiatric symptoms, since early stages of infection [9]. Disorders of consciousness occurred commonly (almost 20%), mostly in older patients and in severe advanced COVID-19 stages, but also headache (14%), dizziness (6%), seizures (0.7%) etc. were reported [9]. Anxiety (8%), depression (5.2%), insomnia (13%), and psychosis (1.3%) were also detected during this study [9]. All CNS analyses performed were negative for the viral RNA in patients who presented neurologic manifestations, therefore the inflammatory response with blood-brain-barrier breakdown seems more probable as a pathogenic mechanism [9].

Based on the literature analysis, a comprehensive evaluation of patients diagnosed with COVID-19 should integrate both somatic and psychological aspects, on short- and long-term. A case series to illustrate this necessity is included in the next chapter of this article, with focus on the methodological and therapeutic dimensions.

METHODS

The primary objective of this article was to analyze psychiatric manifestations in patients with acute COVID-19 infection and in patients during post-COVID-19 phase. All these patients were evaluated by multidisciplinary teams, either during hospitalisation or as out-patients, depending on the severity of their clinical manifestations. The secondary objective was to propose a conceptual framework for the evaluation and treatment of these patients.

In order to attain these objectives, patients presented here were screened positive for COVID-19 infection in the last 6 months prior to their initial psychiatric evaluation. All of these patients were further evaluated to detect any personal history of psychiatric disorders, somatic comorbidities, or significant concomitant pharmacological treatments.

CASE SERIES

The first patient was a male, 75 years old, diagnosed positive for SARS-CoV-2 three days prior to the initial psychiatric evaluation. He had no significant history of somatic diseases or psychiatric disorders, and presented an acute onset of spatial and temporal disorientation, together with disturbance in attention and short-term memory, visual and auditory hallucinations, irritability, sleep-wake cycle disturbance, restlessness and agitation, while being admitted to an ICU department for a severe form of COVID-19. Regarding the blood tests, inflammatory markers (procalcitonin, C-reactive protein, fibrinogen) were increased, and CT scan showed bilateral pneumonia. This patient had a slowly favorable evolution of his respiratory infection, and the severity of his confusional state also gradually declined. Treatment with haloperidol 0.5 mg b.i.d. was initiated and maintained for 5 consecutive days, in order to control his psychomotor agitation and hallucinatory-induced behavior. The patient gradually recovered his attentional and mnestic abilities, as well as his sleep-wake cycle at day 5, while hallucinatory manifestations disappeared. Therefore, psychotropic treatment was discontinued starting with day 6. Follow-up visits took place at day 10 after the first psychiatric examination (when the patient was discharged from ICU), and at day 17 (hospital discharge). Clinical Global Impression – Severity (CGI-S) decreased from 6 to 3 and 1, respectively, and Delirium Rating Scale (DRS, 10-item version) [10] total score decreased from 26 to 5, and 2, respectively. Another visit was planned at day 60 after discharge, and the patient was in good physical and mental health, without blood tests abnormalities, chest-X-ray opacities or psychometric cognitive impairment on Mini-Mental State Examination (MMSE).

Discussion

The "cytokine storm" and the neurotropism of coronoviruses were invoked as potential explanations for neuroinflammation and delirium in COVID-19 patients [11]. Prolonged hospitalization, multiple pharmacological concomitant treatments, corticotherapy, higher age, and social isolation may also be contributing factors to the delirium onset [11]. Regardless of causation, either there is a direct effect of coronavirus or a multifactorial ethiology, delirium should be interpreted as a negative prognosis factor in older patients [12]. In an Italian cohort study with 80 COVID-19 inpatients (mean age 74.7+/-14.5 years), 68.8% had delirium with agitation [11]. A larger study (N=516 inpatients, mean age 78 years, SARS-CoV-2 positive) showed that 14.1% of these patients presented delirium on admission, and the most significantly factors associated with delirium were dementia (OR=4.66), the number of chronic diseases (OR=1.20), and chest-X-ray or CT opacity (OR=3.29-3.35 for multiple/bilateral opacities and single opacity vs. no opacity, respectively) [13]. The rate of in-hospital deaths was higher in patients with delirium (58.9% vs. 33.4%), and a multivariable analysis showed an almost twofold increased hazard ratio for delirium-positive patients vs. non-delirium patients for in-hospital mortality [13]. Another study (N=91 participants) supported an even higher difference of in-patient death in cases with delirium vs. non-delirium (72% vs. 31.8%, OR=3.98) [12].

Based on the data in the literature, special attention should be given in elderly developing delirium while being hospitalised for COVID-19. In our presented case, the evolution was favorable, although the patient was admitted in an ICU unit, and he had bilateral pneumonia. According to a longitudinal study, delirium during the hospitalisation in elderly patients with respiratory failure or shock (N=821) was associated with cognitive impairments on long-term in a significant proportion of the participants, and a longer duration of delirium was independently associated with significant worse global and worse executive function cognition at 3 and 12 months [14]. Therefore, follow-up visits are considered necessary in old age patients with delirium during hospitalisation for COVID-19, with screening for possible long-term psychiatric consequences, especially for neurocognitive impairments.

The second patient was a female, 37 years old, diagnosed with acute psychotic disorder, after two months since her discharge from hospital for COVID-19, with an acute onset of delusions of contamination and incurability ("I am still positive for SARS-CoV-2", "No one can really be ever cured from this infection", "I feel like I am condemned to being sick forever"), somatic hallucinations ("My lungs are pressured and they are getting smaller and smaller", "All my body is aching because the virus is spreading in me"), delusional-induced behavior (continuously disinfecting her environment and her body, repeatedly consulting physicians in spite of the fact that all her COVID-19 tests were negative), and lack of insight into her pathology. These symptoms were correlated by the patient with the re-occurrence of several respiratory symptoms (dyspnea, cough) which were attributed by her GP to a non-coronavirus respiratory infection, without pulmonary negative impact, according to the chest X-ray results. Atypical antipsychotics should be preferred in young and adult population, based on their superior tolerability profile [15,16]. Olanzapine 5 mg q.d. was initiated, and the dose was increased up to 15 mg q.d. during the next 7 days. After two weeks, the patient presented an improvement of her delusions and hallucinations, and of her psychosis-induced behavior. Also, a better insight was detected, as she admitted she may need a psychotropic treatment for her condition, and that there could be a possible psychiatric origin of her symptoms. Follow-up visits were performed at 4, 8, and 24 weeks. The clinical evolution reflected in the Positive and Negative Syndrome Scale (PANSS) score was favorable, with gradual decline in psychotic positive symptoms, from 98 (initial visit) to 80, 67, and 56, respectively. CGI-S score evolution reflected this improvement, with decline from 5 (initial visit) to 2 (at week 24). Global Assessment of Functioning (GAF) scores increased from 40 (initial visit) to 60, 75, and 80, respectively.

Discussion

Evidence from previous pandemics, especially with viral respiratory pathogens, support the correlation between schizophrenia-like disorders and the status of infected patient [17]. In a review of 42 cases of psychosis as acute or post-infectious manifestation of COVID-19 could not find evidence for a specific mechanism of psychosis onset in this population, 4 hypotheses being considered: direct neuronal viral infection, post-infectious neuronal autoimmunity, vasculopathies from impaired coagulation, and systemic effects of a pervasive severe pathogen and/or critical illness [17]. In our case, no biological causal relationship could be established between the COVID-19 disease and the acute psychotic disorder, but a psychological relationship is easy to infer from the available data.

There are several similar reports in the literature about new onset of psychotic disorders in the context of COVID-19 pandemic, e.g. a 38-year-old woman, with no psychiatric history, developed psychotic symptoms caused by fear of SARS-CoV-2 contamination [18]. She started to feel that “a demonic force” visit her at night and tries to possess her soul, while presenting insomnia, auditory hallucinations which became imperative, visual hallucinations, and induced aggressive behavior [18]. She did not have positive SARS-CoV-2 tests or IgM/IgG antibodies against this virus, and after being diagnosed with acute psychotic disorder, treatment with quetiapine 500 mg/day and clonazepam 1 mg/day was initiated [18]. Psychotic symptoms, anxiety and insomnia improved rapidly during the first week of hospitalisation and the patient was discharged [18].

Another case series included 6 patients (3 male and 3 female) with first-episode psychosis, admitted in an Italian hospital during the COVID-19 pandemic lockdown [19]. Blood tests, toxicological screening, SARS-CoV-2 antigen tests, and brain imaging were unremarkable, except for a mild cortical atrophy in a 73-year old male [19]. All patients had a negative psychiatric history, despite their advanced age [19]. Rapid discharge from hospital (less than 14 days) and fast remission of symptoms were observed in this case series after relatively low doses of antipsychotic treatment [19]. The follow-up visits confirmed the remission of psychosis in all these cases, suggesting the correlation between intense psychosocial stress induced by COVID-19 lockdown measures and the abrupt onset of acute psychosis [19].

Regarding the presence of psychotic symptoms in recently-diagnosed COVID-19 patients, a case series (N=3) showed a relatively rapid remission of these clinical manifestations under treatment (9 days, 10 days, and also 10 days, respectively) with antipsychotics (ziprasidone 40 mg/day, ziprasidone 20 mg/day, or haloperidol 15 mg/day, respectively) [20]. A direct causal relationship between SARS-CoV-2 infection and the onset of psychosis was not established in these cases [20].

Therefore, onset of acute, brief psychotic disoders is not uncommon in individuals without psychiatric history and non-positive for SARS-CoV-2 infection, possible triggered by prolonged social isolation during lockdown or quarantine. In patients with COVID-19 infection, psychotic episodes were also reported, without assessing a possible direct causality. In our presented case, the patient recovered from COVID-19, and the most likely trigger for her psychosis was an acute and mild, viral respiratory, non-SARS-CoV-2 infection.

The third patient was a female, 24 years old, diagnosed with panic disorder with agoraphobia, who presented the onset of her anxiety disorder 4 months after the discharge for COVID-19 pneumonia. This patient reported feelings of choking, shortness of breath, nausea, palpitations, dizziness, paresthesias, derealization, and intense fear of dying with abrupt onset and limited duration (5-15 minutes): “I cannot find myself, it’s like I’m in a trance for several minutes”, “I feel like I’m choking… I can’t breathe, and I need to sit down because everything is spinning around”, “I feel my heart is beating erratic, and my legs are numb… I feel nauseated and my belly hurts”, “I think that I will certainly die when this happens”. The frequency of these panic attacks was 2-3 times/week and the patient actively avoided going out in open spaces for fear of getting new panic attacks. When asked about the first time she had these symptoms, she said “panic attacks are like the choking sensations I had when I was hospitalised for COVID-19... I actually believed I have this disease again, so I repeatedly tested myself for COVID infection”. Clinical, chest-X-ray and spirometry could not objectify any respiratory dysfunction, and the RT-PCR (reverse transcriptase-polymerase chain reaction) assay from nasal and pharyngeal swabs for SARS-CoV-2 infection was negative. No other comorbid conditions, either psychiatric, or organic, were detected. Initial GAF score was 50 and Hamilton Anxiety Rating Scale (HAMA) score was 32. Treatment with paroxetine 20 mg q.d. was initiated, and it was increased up to 20 mg b.i.d in the next 7 days, and gabapentin 100 mg t.i.d [21] was also added from day 1. After 14 days the patient was re-evaluated, and GAF score increased up to 65, while HAMA score decreased to 24. The follow-up visits at day 30 and 90 showed continuous improvement on both scales, GAF scores were 70 and 80, while HAMA scores reached values of 16, and 10, respectively. A cognitive-behavioral therapy (CBT) was suggested to the patient since the initial evaluation, but she declined.

Discussion

Anxiety symptoms are not rarely reported in patients diagnosed with COVID-19, even if the respiratory or general status was not severely affected [7]. In a case report, a 38-

year-old man developed recurrent palpitation, worries, shortness of breath, chest discomfort, fear of death, feeling of impending doom which lasted for about 10 minutes; these symptoms first appeared within two days after he was tested positive for COVID-19 [22]. Although he had a mild form of COVID-19, his symptoms of panic persisted after his test became negative [22]. The patient had no psychiatric history, and he was started on sertraline 50 mg/day and clonazepam 0.75 mg/day [22]. Regarding the possible mechanisms of panic disorder onset in COVID-19 patients, various hypotheses have been formulated: respiratory symptoms, like coughs and dyspnea, are very frequently associated with the SARS-CoV-2 infection, so fear conditioning to abnormal breathing patterns, and hypervigilence towards breathing abnormalities may increase the risk of developing a panic disorder in COVID-19 survivors; other somatic factors associated with COVID-19 or its treatment may fuel the worries and anxiety related to personal health [23].

A systematic review and meta-analysis focused on anxiety in the general population during COVID-19 pandemic (n=43 studies) found an estimated prevalence of 25% (vs. 7.3% normally), varying across the different tools used to measure anxiety [24]. Initial or peak phase of the COVID-19 outbreak, female gender, younger age, marriage, social isolation, unemployment, student status, financial hardship, low educational level, insufficient knowledge about COVID-19, epidemiological or clinical risk of disease and lifestyle and personality variables were the most common risk factors for anxiety [24].

In our presented case, the patient re-activated her memories related to the COVID-19 four months later, in the absence of any current respiratory infection. The main focus of her attention were respiratory symptoms, associated with fear of death, triggered by the same feeling she had when she found out she was diagnosed with COVID-19. The evolution of anxiety symptoms under treatment was favorable, even if no CBT was initiated, based on the patient's preference.

The fourth patient was a female, 72 years old, diagnosed with major depressive episode, severe, and she had the onset of her mood symptoms after she was discharged from hospital with a diagnosis of "remitted COVID-19 disease". This patient was already diagnosed with recurrent major depressive disorder for 8 years, but she was in remission for more than 2 years prior to the COVID-19 diagnosis. She invoked the COVID-19-related stress as the only major stressor in her recent history, and her family confirmed the absence of any other stresors in her immediate environment. She said that she felt threatened by this infection and she was afraid she might die: "When I heard I was positive, I immediately though I will die, and I thought I have only a few hours to live... I was almost certain I could not survive this". Although she had a moderate form of COVID-19, which did not require ICU admission, she necessitated psychiatric evaluation after her discharge from hospital, due to specific depressive symptoms, i.e. anhedonia, depressed mood, insomnia, loss of appetite for food, ideas of incurability, and recurrent thoughts of death. New generation antidepressants, with superior tolerability profile, should be recommended in this population [25,26]. Sertraline 50 mg q.d. was initiated, and gradually increased up to 50 mg t.i.d in the next 14 days. Zolpidem 5 mg q.d. for insomnia was also recommended in this case, for 2 weeks. Geriatric Depression Scale (GDS-30) initial score was 23, and decreased to 16 after 14 days, and 8 after two months. GAF scores increased from 40 (baseline value) to 65, and 82, respectively.

Discussion

A cross-sectional, observational study included hospitalised, COVID-19 infected patients (N=93) and their immediate family members (N=54), and its objective was to assess depression, anxiety, and stress symptoms in the given population [27]. Almost one-third of this sample showed high scores on depression and anxiety subscales of DASS21 (Depression Anxiety Stress Scale-21), with 30-45% of the family members presenting higher scores than the patients [27]. Another observational study that used Patient Health Questionnaire-9 (PHQ-9) in adults during the COVID-19 pandemic vs. 2015-2019 period in Canada showed a substantially increase of depression prevalence in the first time interval [28].

There is a debate in the literature regarding the specifics of the post-COVID depression, i.e. if there are neurobiological differences between the commonly diagnosed major depression and the one detected in COVID-19 survivors. Analysis of data from USA (N=91791 respondents to a questionnaire) collected during COVID-19 pandemic showed that age, gender, race, education, and income exhibited an interaction with prior COVID-19 in risk for moderate to severe depressive symptoms [29]. Among people with such mood symptoms, motoric symptoms and suicidality were significantly greater among those with prior COVID-19, and the depression risk increased with greater interval following acute infection [29]. Little evidence are available until now to suggest different pathogenetic substrates for the two types of depression.

In patients with severe mental illnesses (affective disorders and schizophrenia), a systematic review (n=36 studies) tried to detect special needs during the COVID-19 pandemic [30]. A general impairment of the mental health in individuals with severe mental illnesses could be detected, especially in patients with mood disorders, as compared to those with schizophrenia [30]. Symptoms of depression, anxiety, and stress were more pronounced in patients with history of severe mental disorders, and resilience, age, and socioeconomic factors impacted significantly their health status [30].

In the here-presented case, the patient was already known with history of major depression, but she was in remission prior to the onset of COVID-19 symptoms. She clearly admitted that her worries were related to perceived threats to her personal safety and fear of dying, and she considered these worries as the origin of her currently diagnosed depressive episode. Based on her psychiatric history, the need for prolonged treatment with antidepressants is obvious, as it is the need to closely monitor suicidal ideation and severity of depression on long-term. In patients with psychiatric history, COVID-19 infection may be a significant stressor that could re-activate mood disoders, or may aggravate their mental health. Therefore, supplying patients with psychiatric history of depression with adequate information about the COVID-19 disease and increasing their stress resilience is important [30].

The fifth patient was 69 years old, and presented neurocognitive deterioration possible related to COVID-19, after 5 months since the remission of the infectious disease. She was admitted in a hospital due to COVID-19 pneumonia and had a severe evolution, which required an ICU admission for 3 days. After 5 months since COVID-19 remission, her family reported the gradual onset of low attention and memory functioning, social isolation, speech difficulties, spatial disorientation and low involvement in activities of daily living. Neuroimagistic evaluation (CT scan) detected a temporal and parietal cerebral atrophy, and leukoaraiosis at 5 months after discharge from hospital. Unfortunately, no comparison of this result is possible, as no prior cerebral CT or MRI imagery was available. During the initial psychiatric exam, no other comorbidities were detected. Baseline MMSE score was 22, and GAF score was 45. Treatment was initiated with donepezil 5 mg q.d., and the dose increased during the next month to 10 mg q.d., in association with pramiracetam 600 mg b.i.d. The follow-up visits at 3 and 6 months detected no change in the MMSE score, and the GAF slowly increased to 50.

Discussion

Multiple mechanisms for the onset of neurocognitive disorders in COVID-19 survivors have been suggested, e.g. hypoxic brain injury secondary to severe pneumonia; centyral nervous system invasion by coronaviruses via blood circulation or neuronal pathway; immune-mediated injury [31]. Under-detection of delirium in patients with COVID-19 may be a silent contributor to the development of neurocognitive disorders, especially if there are cases of hypoactive delirium [31,32]. Pre-existing delirium and small vessel cerebrovascular disease often detected in elderly may result in greater vulnerability to accelerated cognitive deficits in COVID-19 survivors [33]. In an observational study, the cognitive function was evaluated among individuals with persistent cognitive complaints about 5.5 months after COVID-19 infection [34]. Mild cognitive deficits were detected on tests involving attention, processing speed, and executive function, and 70% of these patients were diagnosed with a mood disorder prior to COVID-19 infection [34]. The pattern of cognitive deficits consists in mild impairments, and the contribution of psychological factors related to COVID-19 infection, as well as residual symptoms may increase the severity of subjective cognitive complaints in this population [34].

In the case we presented, no delirium was diagnosed during the COVID-19 infection, but the patient was admitted in ICU. Lack of any previous neuroimagistic evaluation or cognitive assessment makes it difficult to establish the impact of COVID-19 infection over cognitive function in this case. Increased attention should be given to the existence of delirium (either hypoactive or hyperactive) in elderly patients with COVID-19 infection, and especially if they had severe forms of this disease. Cognitive evaluation in elderly with delirium during hospitalisation, or prolonged hospitalisation related to COVID-19 infection should be included in their monitoring plan.

CONCLUSIONS

Patients diagnosed with COVID-19 may have a high rate of neuropsychiatric symptoms or disorders [35,36], due to the direct, biological impact of the SARS-CoV-2 virus, or due to the psychological stress related to this disease (table 1). The direct effects of COVID-19 over the mental health status is difficult to verify in clinical practice [37,38], and data in the literature does not support such a clear, causal relationship. However, evaluation of the COVID-19-diagnosed patients from the perspective of psycho-social stress consequences could help physicians in the detection of vulnerability factors, which may indicate the necessity for early pharmacological and/or psychotherapeutic interventions.

Patients with prior psychiatric diagnoses, prolonged ICU/hospital admissions, multiple stressors (psychological, social, economic, health-related), or personality vulnerabilities (e.g., reduced coping mechanisms, low tolerability to stressors, anxiety features) may require a psychological screening after acute respiratory symptoms remission. When early signs of psychiatric disorders or isolated symptoms are identified, structured psychiatric evaluation, pharmacologic and/or psychological support should be recommended. Mood symptoms, especially depressive, neurocognitive impairment, anxiety symptoms/ disorders, or psychosis have been reported in COVID-19 survivors, even after several months since the remission of respiratory symptoms. In the acute phase of the COVID-19, delirium and psychosis, but also anxiety or mood symptoms should be actively monitored and adequately treated. Because mood disorders are associated with severe complications, like suicide or addictive disorders [39,40], and neurocognitive disorders have a dramatic impact over patients' and caregivers' quality of life [41], early detection and treatment of these conditions are needed, under constant medical monitoring.

Table 1: Synthetic presentation of clinical and therapeutic characteristics in COVID-19-related psychiatric disorders

Case number	Diagnosis	Scales administered	Treatment	Evolution	Observations
1	Delirium, hyperactive	DRS, CGI-S, MMSE	Haloperidol 0.5 mg b.i.d	Favorable, symptoms remited in 5 days	Hyperactive delirium is easy to detect, but hypoactive type should also be searched for in vulnerable populations
2	Acute psychotic disorder	PANSS, CGI-S, GAF	Olanzapine 5 mg q.d., increased to 15 mg q.d. during 7 days	Favorable, symptoms declined significantly after 2 weeks	Psychological stressors related to COVID-19 may be important for the onset of acute psychosis in patients without psychiatric history
3	Panic disorder with agoraphobia	HAMA, GAF	Paroxetine 20 mg q.d., increased up to 20 mg b.i.d in the next 7 days + gabapentin 100 mg t.i.d.	Favorable, improvements on both scales up to 60 days of follow-up	Respiratory distress during COVID-19 may represent a fixation point for anxiety, and it may be subsequently activated
4	Major depressive episode, severe, without psychotic features	GDS-30, GAF	Sertraline 50 mg q.d., gradually increased to 50 mg t.i.d; zolpidem 5 mg q.d. for insomnia was also recommended	Favorable under treatment, up to 60 days of follow-up	Patients with MDD in personal history may be susceptible to new episodes due to COVID-19 distress
5	Mild neurocognitive disorder	MMSE, GAF	Donepezil 5 mg q.d., increased during the next month to 10 mg q.d.; pramiracetam 600 mg b.i.d	Stable, up to 6 months of follow-up	Cognitive function should be monitored in vulnerable populations after COVID-19 infection.

DRS= Delirium Rating Scale, CGI-S= Clinical Global Impression- Severity, MMSE= Mini-Mental State Examination, Positive and Negative Syndrome Scale, HAMA= Hamilton Anxiety Rating Scale, GDS= Geriatric Depression Scale- 30-item version, MDD= major depressive disorder

In conclusion, psychosocial stressors related to the COVID-19 pandemic (e.g., vital threat, isolation, hospitalisation), direct neurobiological influence of SARS-CoV-2 infection, systemic inflammatory reaction, and individual vulnerability factors (e.g., personal psychiatric history, dysfunctional coping mechanisms) may contribute to a diathesis-stress model for psychiatric disorders onset in patients during the acute phase or after the remission of COVID-19 symptoms.

Analysis of risk factors for antipsychotic-resistant schizophrenia in young patients – A retrospective analysis

Octavian Vasiliu[1], Daniel Vasile[1,2], Andreea F. Făinărea[1], Mihaela C. Pătrașcu[1], Elena A. Morariu[1], Raluca Manolache[1], Iulia Alexandru[1], Flavius T. Androne[1]

Abstract: *Treatment resistant schizophrenia (TRS) is a severely disabling disorder, which decreases dramatically the quality of life and overall functionality, while it increases the rate of hospital admissions and overall healthcare costs. The main objective of this research was to evaluate the risk factors for TRS in a group of patients based on a retrospective analysis. The secondary objective was to design an algorithm for initial evaluation in patients with schizophrenia, in order to detect the candidates at risk for developing TRS. Medical charts and consultation records of all patients aged between 18 and 30, diagnosed with TRS, evaluated during 1-year in our department, were selected for analysis. The most significant risk factors for TRS found in univariate model were younger age at schizophrenia onset, male gender, living in rural areas, co-morbid drug dependence, lower therapeutic adherence, and premorbid personality disorder. Marginally significant were higher Positive and Negative Syndrome Scale (PANSS) scores at previous admissions, higher scores on PANSS negative symptoms sub-scale, and lower educational background. In the multivariate model, TRS was still significantly predicted ($p<0.05$) by younger age at the disease onset, addictive co-morbidity, and lower therapeutic adherence. An algorithm based on these risk factors is suggested, based on (a) structured PANSS evaluation using SCI-PANSS and Informant Questionnaire for PANSS, (b) a scale for the detection of co-morbid drug dependence (i.e. Inventory of Drug Taking Situations, IDTS), (c) an interview for detecting premorbid personality disorders (i.e. Structured Clinical Interview for DSM IV – Axis II Disorders, SCID-II), and (d) Treatment Satisfaction Questionnaire for Medication (TSQM) for therapeutic adherence monitoring. Also, the inclusion of several pharmacogenetic parameters (at least CYP450 2D6 panel for detection of poor/ultrarapid metabolizers) could be useful when establishing an adequate therapeutic management, and may help in decreasing the rate of non-response due to variations in antipsychotics plasma levels.*

Keywords: *antipsychotics, treatment-resistant schizophrenia, pharmacogenetics, therapeutic adherence, co-morbidity*

TREATMENT-RESISTANT SCHIZOPHRENIA IN YOUNG PATIENTS – CURRENT STAGE OF RESEARCH

Young age is an important negative prognosis factor in patients diagnosed with schizophrenia, and individuals aged 26 or less at their first psychotic episode have a higher risk to be treatment-resistant [1]. This phenomenon has significant impact over patients and their caregivers functionality, but also involves higher costs for society, and especially for the healthcare system.

[1] Carol Davila University Emergency Central Military Hospital, Bucharest

[2] Carol Davila University of Medicine and Pharmacy, Faculty of Medicine, Bucharest

Treatment resistant schizophrenia (TRS) is defined by the lack of significant clinical improvement despite therapy with two different antipsychotics from at least two different chemical classes (at least one is an atypical agent) in the previous 5 years at recommended doses for at least 2-8 weeks each drug [2]. Other definitions are more inclusive, stating that resistance is observed when the patient has inadequate response to at least two antipsychotic drugs at the maximally tolerated dose within the recommended therapeutic range in trials of at least 6 weeks [3].

Pseudo-resistance may be attributed to a large spectrum of factors, i.e. lack of therapeutic adherence, co-morbid psychiatric and/or somatic disorders, pharmacokinetic interactions, and pharmacodynamic negative impact of concomitant medication. Also, from a pragmatic perspective, cases of partial response or lack of response may be related to changes of generic antipsychotics, i.e. in patients who take different products (although with the same non-proprietary names) during successive months, due to economic or administrative issues. This observation is supported by at least a literature review which confirms clinical deterioration, adverse effects, and changes in pharmacokinetics associated with generic substitution of several psychotropics, antipsychotics included, while generics do not always lead to anticipated monetary savings and raise compliance issues [4].

To make things more complicated, certain pharmacological strategies could produce ambiguous results, i.e. combining two or more antipsychotic agents is a practice observed in more than 40% of patients with schizophrenia [5]. It's very difficult in these cases to differentiate the effect of each drug, and to monitor the clinical evolution of such patients.

A re-evaluation of the diagnosis is granted in all cases of non-response, and various psychological factors that could worsen the patient's overall status should be addressed by the case manager (i.e. housing instability or homelessness, lack of integration in the medical health system, familial conflicts). Integration of these factors in the therapeutic management of schizophrenia as possible factors for decreasing the response rate should be considered good practice.

Currently it is assumed that one third of the patients who has schizophrenia don't respond to an adequate treatment [6]. Even if these patients are switched on clozapine, after two failed trials with different antipsychotics, up to 40% of them will experience only partial remission, and full functional recovery is impossible for more than half of these individuals [7].

Various predictors for poor treatment response were reported, i.e. severity of negative symptoms, or low level of premorbid functioning [8]. Treatment-resistant patients present glutamatergic abnormalities, a lack of dopaminergic abnormalities, higher familial loading, and significant decrease in grey matter compared to responsive patients, which raises the question if a distinct type of schizophrenia could be detected from the very beggining [8]. An analysis of adult patients with TRS (N=8624) included in the Danish National Registry showed that higher rates of treatment-resistance were observed in younger individuals, living in rural or provincial areas, with lower education level, hospitalised over 30 days in the year before first schizophrenia diagnosis, who were in-patients at first schizophrenia diagnosis, with paranoid subtype, comorbid personality disorder, and/or previous suicide attempt, who used multiple psychotropic drugs (antipsychotics, antidepressants, or benzodiazepines) [9].

Pharmacogenetic studies detected associations between genes polymorphisms in pharmacokinetic (i.e. cytochrome P450 1A2 and 2D6 isoenzymes) and pharmacodynamic (i.e. D2, D4, and 5HT2A receptors) factors, and response to antipsychotics [10]. These genes are involved in various stages of processing and action of antipsychotics, from the hepatic metabolism to generation of various adverse events. If all these factors could be defined on large-scale trials, they could improve the efficacy and tolerability of antipsychotic treatment, in a future personalised medicine. Until then, several studies and case reports linked functionally 5HT3 receptors gene single-nucleotide polymorphisms (SNP) to the clozapine responsivity, and CYP1A2*1F genetic polymorphism to the clozapine metabolism [11,12]. Both these observations could explain several cases of TRS, but larger trials are needed to confirm these reports.

A predictive model for therapeutic response in schizophrenia, based on logistic regression analyses, was suggested, and it showed that 76% of the patients carrying combination of four SNPs will have a lower response to atypical antipsychotic monotherapy [13].

Another interesting suggestion is classifying schizophrenia in different subtypes, based on biological markers, clinical staging (illness severity, prognosis, and therapeutic options), and treatment response [14]. Antipsychotic responsive schizophrenia, clozapine responsive schizophrenia, and clozapine resistant schizophrenia are the subtypes suggested by this model [14]. This classification may have important prognostic value and could help clinicians in formulating an adequate therapeutic management. Unfortunately, no good quality data exist for the next step in the treatment of clozapine-resistant patients, although co-prescribing a second atypical antipsychotic, a selective serotonin reuptake inhibitor, lithium or divalproex, glycine or D-cycloserine, and memantine has been investigated with low to moderate success [15].

Table 1. Demographic and disorder-related variables at the evaluation visit

Variables	Values	Observations
Current age	26.1 (range 18-30)	Only young patients were included in the analysis
Age at onset of the disorder	22.9 (range 18-29)	
Gender		
Female	8	53.3%
Male	7	46.7%
Environment		
Rural	7	46.7%
Urban	8	53.3%
Marital status		
Single (including unmarried and divorced)	11	73.3%
Married	4	26.7%
Social status/income		
High	1	6.7%
Medium	4	26.7%
Low	10	66.6%
Independent living	14	This proportion could be due to the addressability of our department
Institutionalized	1	
Number of previous psychotic episodes	0.6 (range 0-3)	Most of the patients were at their second psychotic episode
Substance related disorders present (nicotine dependence included)	11	9%
Personality disorders present	8	53.3%
PANSS overall score	91.8 (range 86-122)	
PANSS-negative Scale	30.5 (range 15-40)	
PANSS-positive Scale	32.6 (range 20-42)	
Length of the current episode (weeks)	12.5 (range 6-30)	

OBJECTIVE AND METHODS

The main objective of this research was to evaluate the risk factors for TRS in a group of patients based on a retrospective analysis.

The secondary objective was to design an algorithm for initial evaluation in patients with schizophrenia, in order to detect the candidates at risk for developing TRS.

Medical charts and consultation records of all patients aged between 18 and 30, diagnosed with TRS, evaluated during 1-year in our department, were selected for analysis. A number of 15 TRS cases were detected from a total of 68 patients diagnosed with schizophrenia. The diagnosis of TRS was based on DSM IV TR criteria and the World Federation of Societies of Biological Psychiatry Guidelines for Schizophrenia criteria [2].

A logistic regression analysis using SPSS 22.0 was performed on 25 demographic, clinical, and therapeutic variables, in a univariate, followed by a multivariate model. No pharmacogenetic variables could be identified in the selected medical documents.

RESULTS

The most significant risk factors for TRS in univariate model were younger onset age ($p<0.01$), male gender ($p<0.01$), living in rural areas ($p<0.05$), co-morbid drug dependence ($p<0.05$), lower therapeutic adherence ($p<0.05$), and premorbid personality disorder ($p<0.05$).

Marginally significant in the same univariate model were higher Positive and Negative Syndrome Scale (PANSS) score at previous admissions ($p=0.056$), higher score on PANSS negative symptoms scale ($p=0.058$), and lower educational background ($p=0.061$).

In the multivariate model, TRS was still significantly predicted ($p<0.05$) by younger age at onset ($p=0.022$), addictive co-morbidity ($p=0.042$), and lower therapeutic adherence ($p=0.048$).

Table 2. Risk factors for TRS in young adults

Factors	Values	
	Spearman's ρ	**Linear regression p**
Younger age at the current episode onset	0.467	<0.01
Gender – male	0.592	<0.01
Substance-related disorder comorbidity	0.320	<0.05
Living in rural areas	0.367	<0.05
Lower therapeutic adherence	0.322	<0.05
Premorbid personality disorder	0.298	<0.05
PANSS overall score at previous admission	0.155	0.056
PANSS-Negative Scale current score	0.152	0.058
Lower educational background	0.142	0.061

An algorithm based on these risk factors is suggested, based on:

(a) Structured PANSS evaluation based on SCI-PANSS and Informant Questionnaire for PANSS, because the previous PANSS overall scores and current Negative Scale score are correlated with the patients risk for developing TRS;

(b) A scale for the detection of co-morbid drug dependence (i.e. Inventory of Drug Taking Situations, IDTS), because current drug-related disorders should be integrated in the therapeutic management, and it has prognostic value;

(c) An interview for detecting premorbid personality disorders (i.e. Structured Clinical Interview for DSM IV – Axis II Disorders, SCID-II), because of the correlation between the risk for TRS and several premorbid disorders (especially cluster A disorders);

(d) Treatment Satisfaction Questionnaire for Medication (TSQM) for the monitorisation of therapeutic adherence, because a low therapeutic adherence is a major risk factor for developing treatment-resistance

Also, the inclusion of several pharmacogenetic parameters (at least CYP450 2D6 panel for detection of poor/ultrafast metabolizers) could be useful when establishing an adequate therapeutic management, and may help in decreasing the rate of non-response due to variations in antipsychotics plasma levels. This could have important pharmacoeconomic impact, since many antipsychotics undergo hepatic metabolism, not to mention the risk of potential pharmacokinetic interactions between antipsychotics, or between antipsychotics and other co-administered drugs.

CONCLUSIONS

Analysis of risk factors for TRS should be included in an evaluation algorithm for all patients diagnosed with schizophrenia. While some risk factors could not be influenced therapeutically, still others can be addressed, with targeted intervention for co-morbid addictive disorders, personality disorders, negative symptoms, or with techniques for increasing therapeutic adherence.

Anatomical study of the anterolateral ligament in Romanian population

Radu Paraschiv[1], George Dinache[2,3], Mark E. Pogarasteanu[2,3], Sorin Lazarescu[1]

Abstract: *The purpose of this paper was to evaluate the existence of the anterolateral ligament of the knee in the Romanian population. Multiple studies have investigated the anterolateral structures of the knee, but there is some inconsistency regarding the existence of the anterolateral ligament.*

Materials and methods: A cadaver dissection study was performed on 10 knees (5 left and 5 right), 3 males and 2 females

Results: The anterolateral ligament was observed in all 10 knees. The mean length was 32±6mm, the width was 5.1±2 mm, and the thickness at the articular line was 1.1±5 mm.

Conclusions: A 100% presence was found, with a slight difference from the length, width, and thickness in other countries, race not being a decisional factor in differences.

Keywords: *anterolateral ligament, anatomy, lateral collateral ligament, dissection*

INTRODUCTION

In the year 1879, the French surgeon Paul Segond [1] described the existence of a fibrous band laying on the anterolateral facet of the knee. Until this moment in the specialty literature, we find ambiguous naming of this band, like lateral capsular ligament [2], the osseous-capsular layer of the iliotibial band [3, 4], or anterolateral ligament [5]. In this study made on 10 knees from the cadavers from The "Carol Davila" University of Medicine and Pharmacy Bucharest, there had been studied the femoral origin and tibial insertion, the trajectory and anatomical rapport with neighboring structures. So the anterolateral ligament was found like being a distinct ligamentous structure on the lateral facet of the knee, anteriorly its origin is on the lateral femoral epicondyle anterior of the collateral ligament and insertion on the anterolateral facet of the tibia at the half distance between the tibial tubercle and Gerdy's tubercle, being distinct of the iliotibial tract, with an oblique trajectory from its origin towards the insertion.

The knee joint is the largest joint in the body, and the following structures that are contributing to its stability are anterior and posterior cruciate ligament, medial and lateral collateral ligaments, quadriceps tendon, patellar tendon, popliteus tendon, and the anterolateral ligament [6].

MATERIALS AND METHODS

In this study were used 5 cadavers (10 knees), 3 males and 2 females. The mean height was 170 cm, the mean weight was

62 kg, and the mean age was 75.1. For the dissection, three incisions were made: two circumferential in the medial 1/3 of the thigh and the medial 1/3 of the calf and 1 sagittal incision on the anterior aspect of the knee. The skin and subcutaneous tissue were removed using these incisions. The lateral vastus and iliotibial tract were detached. Once the lateral collateral ligament was shown, the tibia was internally rotated and the knee flexed to highlight the anterolateral ligament. Once shown, the knee was extended, and the origin and insertion of the ALL were marked, its length, width, and thickness were measured.

Figure 1: Superficial layer of the knee

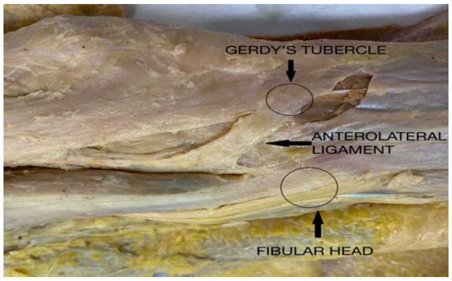
GERDY'S TUBERCLE
HEAD OF THE PERONEUS
BICEPS TENDON

Figure 2: Dissection of the superficial layer



GERDY'S TUBERCLE
ANTEROLATERAL LIGAMENT
FIBULAR HEAD

RESULTS

The anterolateral ligament was observed on the anterolateral aspect of the intraarticular capsule of the knee after the detachment of the iliotibial tract. The ALL appeared as a white thickening that could be seen without a microscope and can be palpated. ALL was shown in all the 10 knees (5 right knees and 5 left knees).

Table 1: Prevalence of anterolateral ligament in the Romanian population

Total	Right	Left	Female	Male
100 % (5/5)	100 % (5/5)	100 % (5/5)	100 % (2/2)	100 % (3/3)

The origin of the ALL is at the lateral femoral epicondyle, posteriorly from the popliteus muscle-tendon, and has an oblique trajectory towards its insertion on the tibial plateau, and the half distance between de fibula head and Gerdy Tubercle. Fibers from the ALL insert on the lateral meniscus. ALL insertion is at 16±4mm anterior of the fibula head. Once the knee is extended the length was 32±6 mm, the width was 5.1±2 mm, and the thickness at the articular line was 1.1±5 mm.

REFLECTED BICEPS TENDON

Table 2: Prevalence of anterolateral ligament in the Romanian population

	Female	Male	Total	P-value
Length (knee extended)	33 ± 5.9 mm	31.6 ± 5.8 mm	32 ± 6mm	0.56
Width (articular line)	5.2 ± 2.2 mm	5 ± 1.8 mm	5.1 ± 2mm	0.78
Thickness (articular line)	1.2 ± 5.3 mm	1 ± 4.8 mm	1.1 ± 0.5 mm	0.16

There were multiple researches conducted regarding the presence and anatomical features of the anterolateral ligament in various populations. We choose a few studies that we considered more relevant for our ethnicity and we compared them with our study. Our results were similar with some of them (Kennedy et al (2015), Vincent et al (2012)), but others described the presence of the ALL in a minority of cases – Potu et al (2016), Roessler et al (2016)) – as it is seen in Table 3.

Table 3: Anterolateral ligament prevalence in the world

Autor (year)	Subject (nr)	Population (mean age)	Prevalence (%)	Lenght (mm)	Width (mm)	Thickness (mm)
This study	Cadaver (5)	Romania (75.1)	100	32 ± 6	5.1 ± 2	1.1 ± 0.5
Dodds et al (2014)	Cadaver (40)	UK (75)	83	59 ± 4	6 ± 1	
Kennedy et al (2015)	Cadaver (15)	USA (58.2)	100	36.8		
Vincent et al (2012)	Cadaver (10)	France (85.3)	100	34.1 ± 3.4	8.2 ± 1.5	2-3
Runer et al (2016)	Cadaver (44)	Austria (78.1)	45.5	42.2 ± 6.2	5.6 ± 1.3	1.2 ± 0.3
Claes et al (2013)	Cadaver (41)	Belgium (79)	97	38.5 ± 6.1	6.7 ± 3.0	1.6 ± 0.6
Helito et al (2013)	Cadaver (20)	Brazil (61.5)	100	37.3 ± 4.0	7.4 ± 1.7	2.7 ± 0.6
Caterine et al (2015)	Cadaver (19)	Canada (70)	100	40.3 ± 6.2	5.1 ± 1.8	1.4 ± 0.6
Potu et al (2016)	Cadaver (24)	Caucasian	4.16	34.23	4.04	1.78
Roessler et al (2016)	Cadaver (20)	Germany (79.4)	60	39.63 ± 0.78	5.28 ± 0.33	1.52 ± 0.31

DISCUSSION

Although the number of cadavers selected in this study was low (five cadavers), one of the most important observations was that the anterolateral ligament was highlighted on all 10 knees. In the specialty literature until now there was shown inconsistency in discovering the ALL [7-9]. After Claes et al. [5] conducted the study, the anterolateral ligament began to get high importance and from this more studies had been made, but had uncertain results. While some authors redact that they have a 100% prevalence rate for ALL [10-13], others describe its presence in a minority of cases [7-9]. Another important detail is that the anterolateral ligament is a capsular-ligamentous structure in the lateral aspect of the knee, and although many studies were made, some of them discovered the absence of this structure [14-16]. Seebascher described that the lateral facet of the knee has three layers [17], and Getwood said that the ALL is situated in the Seebacher layer [18]. Through the dissection of the cadavers, I had concluded to agree with Getwood and that the anterolateral ligament is situated proximal attached to the lateral epicondyle and distally to the lateral plateau, having fibers that unite with the lateral meniscus. Regarding other studies, in our dissection, we found the presence of the anterolateral ligament in all the 10 knees (5 right and 5 left knees). The study also demonstrated a shorter, thinner, and narrow ligament comparative with others. The mean length was 32±6 mm, 33±5.9 mm in females, 31.6±5.8 mm in males. The mean width was 5.1±2 mm, 5.2±2.2 mm in females, 5±1.8 mm in males. The mean thickness was 1.1±5 mm, 1.2±5.3 mm in females, 1±5.3 mm in males. It couldn't be demonstrated a significant difference between sexes.

CONCLUSIONS

The study was conducted to confirm the presence of the ALL in the anterolateral region of the knee and to analyze its anatomical characteristics using Romanian cadavers. A 100% presence was found, with a slight difference from the length, width, and thickness in other countries, race not being a decisional factor in differences. Therefore, the capsular thickening thas has been controversial with its naming can be called the anterolateral ligament.

Anatomic-surgical study on the interparietoperitoneal space from a laparo-endoscopic perspective

Daniel Ion[1,2], Alexandra Bolocan[1,2], Ruxandra D. Sinescu-Bălțățeanu[1,3], Octavian Andronic[1,2], Ana-Maria Oproiu[1,4], Adelina Popa[1,5], Mihai C. Dumitrașcu[1,6], Dan N. Păduraru[1,2]

Abstract: *The interparietoperitoneal (IPP) space, by a broad definition, is the space between the musculo-fascial walls of the abdomen and the parietal peritoneum. A review of the literature on this subject has been performed through a search in the databases according to the following keywords: Bogros space, Retzius space, preperitoneal approach, and urogenital fascia. We have also analyzed the video recordings of the dissections of the inguinopreperitoneal region during TAPP, conducted by a single team, evaluating the dissection planes in the two compartments (medial and lateral) of the IPPS. Based on the latest data from the literature, as well as on our own experience in laparo-endoscopic herniation surgery, we aim to provide answers to several questions. IPPS from the inguinal region is an area as complex as it is narrow, but of great current surgical interest (approaches of hernias, vessels, prostate). The fascial distribution has its origin in the embryological development of the urogenital apparatus. The basic fascial structure in understanding IPPS compartmentalization is the UGF, along with its extensions.*

Keywords: *interparietoperitoneal space, Bogros space, Retzius space, preperitoneal approach, urogenital fascia*

INTRODUCTION

The interparietoperitoneal (IPP) space, by a broad definition, is the space between the musculo-fascial walls of the abdomen and the parietal peritoneum.

In classic anatomy descriptions, it is depicted as a virtual space, filled with adipose/fibroareolar tissue [1]. It is Bogros' merit to have broadened the perspective on a portion of the IPPS in 1823, one of only 13.5/15.5 mm, through which continuity between the anterior and posterior IPP space is obtained [2].

Bogros' initial description was in relation to the inferior epigastric artery and went along the lines of: “a loose layer of cellular tissue separating the inferior epigastric artery from the transversalis fascia anteriorly. Posterior, a thicker layer of the same tissue separates it from the peritoneum” [3].

We could therefore call this space located immediately below the FT (Fascia transversalis), where Bogros recommends the approach of the epigastric artery, as "original sp. of Bogros". The term Bogros space was given to it by Poirier as late as 1912 [4]. In 1858 the Swiss Anders Adolph Retzius described the so-called prevesical space as a compartment of the extraperitoneal space (a division of the at-large extraperitoneal space), as it turns out, without the knowledge of Bogros' work [5]. Since then, the two compartments of the IPPS have long been debated in anatomical literature.

A “historical review” of the authors who endeavored with the anatomical clarification of the IPPS, in terms of

delimitations, content, and surgical applications, was made by R.C. Read [6]. The laparo-endoscopic approach of interparietoperitoneal space has brought many clarifications concerning regional anatomy, through in vivo exploration, obtained by magnification using specific optical instrumentation.

Based on the latest data from the literature, as well as on our own experience in laparo-endoscopic herniation surgery, we aim to provide answers to several questions:

- Which is the structure described by Bogros as a "loose layer of cellular tissue" in the first part of the quote?

- Which is structure described as a “thicker layer”?

- Is there an anteroposterior division of the Bogros space?

- Is the Retzius space a continuation within the same plane of the Bogros space?

- Which are the landmarks in terms of the fasciae for optimal dissection during the transabdominal preperitoneal laparoscopic (TAPP)/totally extraperitoneal laparoscopic (TEP) approach?

MATERIALS AND METHODS

A review of the literature on this subject has been performed through a search in the databases according to the following keywords: Bogros space, Retzius space, preperitoneal approach, urogenital fascia.

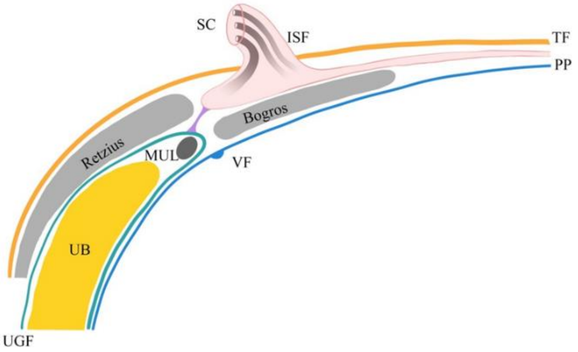
We have also analyzed the video recordings of the dissections of the inguinopreperitoneal region during TAPP, conducted by a single team, evaluating the dissection planes in the two compartments (medial and lateral) of the IPPS.

RESULTS

Ever since 1965, R Stoppa has approached the inguinal pro-peritoneal space by median sub umbilical incision, to carry out the prosthetic procedure called giant prosthetic reinforcement of the visceral sac (GPRVS). Dissecting the sperm cord elements in the IPPS, he described the internal spermatic fascia as an extension of the urogenital fascia [7].

This latter structure is the key to understanding the layout of the anatomical elements within Bogros and Retzius spaces. Embryology data show that the two layers of the UGF are a direct continuation of the renal fasciae, the anterior one (Gerota) and the posterior one (Zukerkandl), in-between themselves containing the urogenital elements developed from the mesonephros (kidneys, adrenal glands, gonads, ureters, ductus deferens), as well as the vessels and nerves that serve them, being compared to a border of these organs [8]. In the 5-week-old embryo, the mesonephros is attached to the posterior abdominal wall through a "broad urogenital mesentery" [9]. One must mention here that the urinary bladder and the urachus have another embryonic origin, which is the cloaca and allantois respectively, so they are located behind the UGF (Figure 1).

Figure 1: IPPS from the “new perspective” of TAPP



UGF – Urogenital fascia; MUL – Medial umbilical ligament; UB –Urinary bladder; SC –Spermatic cord; ISF – Internal spermatic fascia; TF – Fascia transversalis; PP – Parietal peritoneum; VF – Vesicular fold

Therefore, the presence of the UGF in the IPPS sub-divides the two compartments – medial and lateral into another two – superficial and deep, as shown in the following diagram (Table 1):

1 – the superficial medial compartment is the actual Retzius space, previously delimited by the FT (superior)/pubic (inferior) and posterior to it by the UGF.

2 – the deep medial compartment is limited by the UGF anterior to it and peritoneum posterior to it, containing the urinary bladder/urachus and the medial umbilical ligament (MUL), and also known as the perivesical space.

3 – the superficial lateral compartment between the FT (bilaminated) in the anterior plane and the UGF contains the initial portion of VEI, femoral vessels, and genito-femoral nerves. It is the compartment in which Bogros suggested the approach of the inferior epigastric artery be performed.

4 – the deep lateral compartment, delimited by the UGF in the anterior plane and the parietal peritoneum in the posterior plane, i.e., "the new Bogros space".

Table 1: IPPS – Interparietoperitoneal Space Compartments

	Medial	Lateral
Superficial	Retzius prevesical space	Old Bogros space
Deep	Prevesical space	New Bogros space

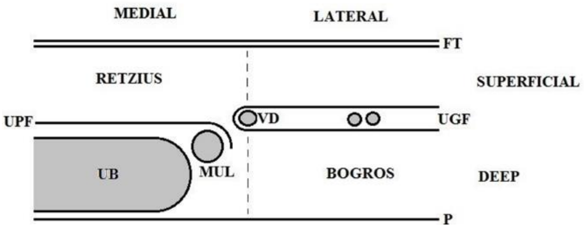
From this perspective, the structure described by Bogros as “a loose layer separates the inferior epigastric artery from the transversalis fascia" is now understood to be the FT's posterior layer, as described by Cooper. The structure described as "a thicker layer" is identified today as the UGF, having as well a bilaminated structure [10].

Anatomical descriptions of the IPP are sometimes confusing because the posterior layer of FT is often described as fused with or identical to the anterior layer of the UGF [11].

The two extensions of the UGF – the spermatic fascia and the umbilical-prevesical fascia have a connection/continuity area at the level of the umbilical artery origin point in the internal iliac artery located in front of the sacroiliac joint. This could correspond to the peritoneal fold visible during TAPP exploration and is described as a "transverse vesicular fold" [12].

From the laparo-endoscopic perspective of inguinal hernia, the Retzius space was located anterior to the UGF, and the new Bogros space was posterior to it (Figure 2).

Figure 2: IPPS Diagram



In the TAPP approach of indirect inguinal hernia, medial dissection is therefore conducted anterior to the UGF, the mark being the MUL located posterior to it. In TEP, one arrives from the retromuscular space in the avascular Retzius space penetrating the posterior rectus sheath [13].

Wandering medial to the posterior space of the UGF leads to bleeding from perivesical venous plexus or even to opening the bladder!

Regarding the creation of the new Bogros space during the laparo-endoscopic approach, our own experience has shown that the most suitable place to initiate the lateral compartment dissection is lateral to the deep inguinal opening, advancing towards the iliac spine in strict contact with the parietal peritoneum. If the dissection is started from the iliac spine, it most often determines the sectioning of the entire peritoneo-fascial cover, revealing the muscular fibers of the transversus abdominis and a variable degree of bleeding from the muscular branches. As one descends towards the ilio-pubic tract, the risk of bleeding from "the Bendavid venous circle" is added [14]. Therefore, lateral compartment dissection should aim strictly for the space between the peritoneum and UGF.

There are authors [15] with descriptions of the dissection plane in the two compartments (medial and lateral) similar to ours, but who use the term "preperitoneal tissue" or "areolar tissue" to denote what we consider to be the UGF or its prolongations.

In a sagittal section, the two spaces, Retzius and Bogros, are located anterior and posterior to the UGF, hence the confusion of some authors who speak, in general, of IPPS and properitoneal space without specifying the differences between the two compartments, the medial and the lateral [16].

Laparoscopic anatomy data of the IPP are confirmed imagistically in various pathological entities involving this region [17-22]. Osteoporosis of different etiology, especially in obese people has multiple anatomical implications for this region through fractures and defective post-healing remodeling, so the surgical approach to this region must be correlated with the condition of the patient [23]. An interesting area of future research is the possibility that the miscarriages occurring in the context of a uterine septum may be explained by the poor vascularization of fibromuscular tissue composing the septum and the approach of the IPPS from the inguinal region can treat the problem with less invasive surgical procedures [24]. Therefore, the prosthesis placed via TAPP or TEP in the Retzius and Bogros spaces is located anterior and posterior to the UGF [25].

DISCUSSION

- The IPPS from the inguinal region is an area as complex as it is narrow, but of great current surgical interest (approaches of hernias, vessels, prostate).
- The fascial distribution has its origin in the embryological development of the urogenital apparatus.
- The basic fascial structure in understanding IPPS compartmentalization is the UGF, along with its extensions.
- Starting from the requirement of reuniting the anatomical terms in this matter we suggest the following equivalents:

- preperitoneal/properitoneal space = interparietoperitoneal space (IPPS)
- old Retzius space= is the space between the UB and FT/pubic branch
- new Retzius space = the space between the UGF and FT/ pubic branch
- old Bogros space = the space between FT and the UGF
- new Bogros space = the space between the UGF and the parietal peritoneum
- UGF = preperitoneal fascia = retroperitoneal fascia.

An organizational chart of an Emergency Health Operation Center

Athanasios Zafeirakis[1], Panagiotis Efstathiou[2]

Abstract: *Nowadays, a wide range of natural and man-made disasters, disease outbreaks and pandemics give rise to health emergencies at a global level. Thus, a health security strategy is urgently required through central planning. At the national level, that vision can be implemented with a properly organized and fully functional Emergency Health Operation Center (EHOC). The main executive sections of an EHOC are Command, Planning, Operations, Logistics, Administration, Communications/Intelligence, and Reporting/Briefing. Each of the above sections has several functions and sub-functions, all operating according to a concrete legal basis and detailed operating procedures.*

Keywords: *emergency planning, public health, operation center, health crisis*

INTRODUCTION

In our epoch, due to the extreme complexity of the modern age, natural and man-made threats the management of health crises should imply an effective and integrated action plan, qualified with characteristics that define the effectiveness and success of such a system. An EHOC is such a system that can lead and coordinate the overall national medical response in every emergency incident, especially when involving mass casualties that either exceeds the management capabilities of the nation's health mechanism or disorganize the existing procedures planned for routine conditions. A successful EHOC should be based on two pillars: Legal authority and organizational structure; both will be herein briefly discussed.

DISCUSSION

Legal authority

The legal authority of an EHOC refers to the development of a concrete legislation directive for the public health authorities as regards roles, responsibilities, and coordination with national disaster management resources for legal health operations. That legislation should establish policy guidance, officials of the government and involved organizations, and other executive officers and professionals tasked to provide leadership at a strategic level. The legal authority of an EHOC varies among countries, while the key governmental agencies usually involved are unfortunately often scattered in various Ministries. The long list of those national agencies includes, but is not limited to the following: Fire Brigade; Police; Ministry of National Defence; Coast Guard; Ministry of Transport and Communications; Civil Airlines; Medical School Laboratories; National Public Health Organization; National Center for Emergency Assistance (NCEA); Hospital units (public and private); National Atomic Energy Committee; Forensic Services; Ministry of Foreign Affairs; Non-governmental healthcare and humanitarian responders [1]. The concomitant spread of leadership centers combined with defective multi-ministerial coordination has been proved devastatingly ineffective in the last decades in many environmental or man-made disasters throughout the world. Hence, an EHOC

must be set under a unified command, a sort of an all-hazard ministry or deputy ministry "of Interior Threats", or "of Civil Protection"; that Ministry can substitute roles, authorities, personnel, and infrastructure of other Ministries and also replace at the highest level both the GSCP and all sorts of emergency committees, mechanisms and operation centers of other Ministries.

Organizational structure

An EHOC should operate within the framework of a thoroughly planned national incident management system, with dedicated personnel and a consolidated operational terminology. Organizational prerequisites for such a system are described in detail in relative handbooks [2-4] and involve at minimum the following executive sections:

1. Command
2. Planning
3. Operations
4. Logistics
5. Administration
6. Communications/Intelligence
7. Reporting/Briefing

The function of an EHOC should be based on competent personnel and equipment installed in a capacious building, consisting of at least an operation-command room, a communication room, and a multipurpose meeting room. The operational doctrine of an EHOC is based on the C4-I principle, i.e. Command – Control – Communication – Coordination – Intelligence. These procedures are prioritized for the planning and response to potential public health risks, albeit they do not replace the daily operational control of resources and services. The goal of C4-I is operational cross-disciplinary coordination at the regional, national and international level and is an integral part of the Concept of Health Operations [5]. Each of the above sections has several functions and sub-functions, (data illustrated in Figure 1), operating according to relevant response actions, called Standard Operating Procedures (SOPs), as described below:

1. Command Section: The EHOC director exerts ex officio the vertical, unified command. He/she is a senior medical officer, with documented expertise in the field of Health Crises and with vast experience in managing complex health operations. The EHOC director will be subordinated to the GSCP and will be supported at his command by a deputy director. Two branches are straight subordinated to the EHOC director:

a) A *Legal Operations Unit* (LOU), staffed by dedicated legal advisers, supports the EHOC leader in taking complicated decisions without unacceptably high legal risks (mainly in emergencies, when some regulations of normal life might need to be temporarily revised or suspended for EHOC operations to be carried out).

b) The *Ancillary Services Unit* (ASU), a supportive bundle of services. Apart from full secretarial support, that unit covers personnel's health, safety and security, cleaning, and janitorial affairs of buildings.

Apart from managing, coordinating, and collaborating skills, the EHOC director must be able to set and follow priorities and optimize results based on available resources. A thorough presentation of the required qualifications of an EHOC director is described by Efstathiou et al [6]. The EHOC director is responsible for the following specific functions:

- The overall operational function and legal responsibility of the EHOC.

- The application of effective command systems, which clearly define roles and responsibilities for all EHOC staff.

- The final responsibility for verification of any possible health event, mobilization of the national mechanism, and information of government. That highly demanding decision is accomplished through the systematic gathering of relevant information from various sources, such as operational contacts, expert networks, printed reports, and media information.

- The coordination (called "interoperability") among EHOC's sections and also between EHOC as a concrete system and any participant organization, including local and private agencies, when a major health incident/operation takes place. As major participants, apart from the national agencies are considered the following international stakeholders:

- Center for Disease Control and Prevention (CDC), with worldwide action; a European-CDC, as well as national CDCs also exist (Planning Section, bellow).
- Monitoring and Information Center (MIC): The operational heart of the United Nations Health Security Committee; mobilizes international aid for mass disaster incidents.
- World Health Organization (WHO): Provides the ultimate health assistance worldwide.
- North Atlantic Treaty Organization (NATO): An intergovernmental military alliance, also providing some specific health standardization agreements (STANAGs).

2. Planning Section: It emphasizes coordination, interoperability, and cooperative team working through relevant SOPs, with the following branches and sub-functions:

Figure 1: Organizational structure of an EHOC

ASU: Ancillary Services Unit
CCT: Casualties Collection Team
CGRU: Cost and General Resources Unit
CIT: Casualties Identification Team
CU: Communication Unit
DACT: Disaster Assessment and Coordination Team
DMATs: Disaster Medical Assistance Teams
DMU: Data-base Management Unit
DTAU: Disaster Technical Assistance Unit
DVIMU: Disaster Victim Identification / Mortuary Unit
EMCU: Emergency Medical Services Unit
ETU: Exercises and Training Unit
FPU: Food Provisions Unit
FU: Facility Unit
H-CDC: Hellenic Disease Control and Prevention Unit
HRU: Human Resources Unit
LOU: Legal Operations Unit
MFCT: Mass Fatality Care Team
MHT: Mental Health Team
MPIT: Media and Public Information Team
MRU: Medical Resource Unit
MSU: Medical Supplies Unit
PHEP: Public Health Emergency Response Planning Unit
PMCT: Post-mortem data Collection Team
RAU: Risk Assessment Unit
RECs: Regional Emergency Coordinators
SCHPT: Shelter Care and Humanitarian Priorities Team
SNSS: Strategic National Sanitary Stockpile
TCCTs: Trauma and Critical Care Teams
VCT: Veterinary Care Team
VIT: Victim Information Team

a) *Risk Assessment Unit* (RAU); as a component of a comprehensive risk management program, RAU conducts hazard-specific vulnerability analyses according to the following flow-chart: Information gathering – data analysis – assessment – prioritization of actions – follow up of resultant outcome.

b) *Medical Resource Unit* (MRU); it predicts the local needs in medical resources, supervises hospital operation in emergency status, and registers medical devices, pharmaceutical stock, beds and bedding, laboratory capabilities, supplies and reserves, personal safety equipment, bio-safety facilities, etc.

c) *Public Health Emergency Planning Unit* (PHEP); it devises hazard generated procedures, priorities and risks, preparedness programs, and all relevant SOPs, both hazard- and response-specific, in a form of an operation manual or handbook. Expected activities are described in flow-chart diagrams and regard all actions to take place from the first hour up to several weeks after the incident. Such SOPs exist for all levels of response and describe, among others, personnel, equipment, supplies and also define operational time points. In their standard form, SOPs include a basic plan describing current legislation, operational phases, and appendices describing incident functions, response specific and deactivation plans, checklists, templates, job cards, resources, and relevant literature [7].

d) *Disease Control and Prevention Unit* (CDC); the national link to the European-CDC.

e) *Exercises and Training Unit* (ETU) for continuous and efficient training of the EHOC staff according to international standards [8]; ETU also conducts preparatory planning for future emergency response scenarios, reviews existing national and international regulations, frameworks, and planning guidelines, and organizes periodically full-scale exercises on a realistic base. A final goal for ETU is an overall improvement of awareness, competence, operational readiness, and continuous updating of plans and procedures.

3. Operations Section: The cardinal EHOC branch comprises preparedness and response activities provided by trained personnel capable of responding within two hours after identification of a major health incident. Specific SOPs are:

- Gathering and analyzing all relevant pieces of information.
- Stepwise analysis and evaluation of all factors affecting the mission; in these are included not only medical factors but also general ones (environment, weather conditions, available time, humanitarian implications, cooperation reluctance or conflict of interest among various public and private participants, staff security, etc).
- Consideration of all alternative case-based actions; that is called mitigation, i.e. threat/hazard/disease-specific, on occasion, actions to minimize health-related impact after hazard occurrence.
- Activation of preparedness levels, from Level 3 (lowest) up to Level 1 (highest), according to the existing situation after interaction with bio-surveillance laboratories network and with the national response framework given by GSCP. The preparedness SOPs include a detailed and continuously updated catalog of involved personnel, methods of fast recall on a 24h/7d basis, key-persons, and all other necessary details of an early warning protocol.
- Flexibility, surge capacity, i.e. ability to respond in multiple emergency health incidents, surge capability, i.e. ability to cope with unusual/special medical needs, and adequate durability, i.e. long-lasting response [9].
- Close collaboration and engagement with scientific entities in strategic preparedness and tactical operations, such as associates from the academic world, seismologists, meteorologists, building engineers, forensic scientists, laboratory experts, anthropologists, epidemiologists, etc.
- Linkage and integration of healthcare volunteers, non-governmental organizations, and major humanitarian responders, e.g. Red Cross.
- Recovery actions at multiple levels, which restore the stricken environment to as close to former “normal” status after a major health incident.
- Promotion of environmental health, social engagement, mobilization, and solidarity of the community.

Hence, according to the above functions the Health Operations Section acts in the following response stages: Incident recognition – Notification – Activation – Mobilization – Operations – Demobilization - Transition to recovery. The Operations Section is divided into several branches [9], as follows:

a) *Regional Emergency Coordinators* (RECs), acting as operational liaisons between central EHOC and the corresponding regional departments of Civil Protection for each of the administrative districts of the nation’s territory; for each REC there should be established a mobile (in a vehicle) operation center with satellite intercommunication with the regional Civil Protection liaison.

b) An *Emergency Medical Services Unit* (EMCU); which is a field-level rapid deployment medical force subdivided into three (3) Trauma and Critical Care Teams (TCCTs). Depending on the incident, these teams can be reorganized in equipment and staffing to Disaster Medical Assistance Teams (DMATs) [10]. DMATs provide primary and acute care, triage of mass casualties, initial resuscitation and stabilization, advanced life support, and preparation of sick or injured for evacuation. All victims are managed by use of the internationally standardized procedure of colored cards which illustrate a brief medical history and mainly the medical priority for each victim (by the respective color). After prompt evacuation from the disaster area (when it is such), a rapid pre-hospital triage, followed by emergency initial stabilization and then by urgent transport of casualties constitutes the operational "holy trinity" for these teams. At the disaster point the TCCT/DMAT leader should be the first official responder who will undertake the following SOPs:

- Rapid estimation of hazard situation on the operation field along with an estimation of a probable number of casualties.
- Prompt notification to his/her superiors about urgent requirements in staff and equipment (ambulances, bedding, paramedics, body bags for fatalities, cold storage facilities, drinking water supply, etc.).
- Together with the (non-medical) on-site delegate of Civil Protection, they immediately delineate operational disaster zones around the disaster point.
- Outside the "hot zone" the above two operational delegates minister to the needs of less injured victims; the TCCT/DMAT leader, in particular, activates the operational teams of sub-paragraphs (c-g) of the EHOC Operation Section (described below).
- Remains in the "hot zone" and coordinates the rescue teams until he/she receives a replacement order.

c) A *Disaster Technical Assistance Unit* (DTAU), consisting of non-medical technical specialists who will provide, support, and repair mechanical and electrical equipment of operation.

d) A *Shelter Care and Humanitarian Priorities Team* (SCHPT); it coordinates humanitarian affairs, especially of the more vulnerable population groups, and prioritizes on-site non-medical, but still life-threatening needs that can heavily affect a disaster area, such as shelter, covers, safety, nutrition, drinkable water, etc. This unit cooperates with the Construction/Engineering Branch of the Civil Protection for shelters and sanitation systems construction.

e) A *Mental Health Team* (MHT), consisting of psychiatrists, psychologists, and social workers. They assess early post-disaster stress within the affected population and responders and support their mental health status by interventional and/or pharmaceutical practices and by cooperation with corresponding church/religion representatives.

f) A *Disaster Victim Identification/Mortuary Unit* (DVIMU); provides expertise, technical assistance, and support for casualties and human remains documentation, in collaboration with the Reporting/Briefing Section of the EHOC (described below). The unit further develops four operational branches; the Casualties Collection Team (employs laborers), the Post-mortem data Collection Team (collects and evaluates fingerprints, DNA/dental samples, etc, for forensic medicine purposes), the Casualties Identification Team, and the Mass Fatality Care Team (offers disaster mortuary services).

g) A *Veterinary Care Team* (VCT); offers care to animal casualties and to operating animals (e.g. rescue dogs), using veterinary medical support, equipment, supplies, and pharmaceuticals.

4. Logistics Section: It determines and supervises the provision of emergency resource needs for the unceasing operational function of the EHOC on a 24h/7d basis. It is divided into the following branches:

a) *Cost and General Resources Unit* (CGRU); it monitors cash flow and expenses and coordinates all sources of funding. Additionally, it can provide direct cash from a special account for immediate access in urgent needs of high priority, thus avoiding time-consuming bureaucracy.

b) *Medical Supplies Unit* (MSU); it monitors needs and provides required quantities of medical and pharmaceutical supplies as well as personal protective equipment for frontline health care workers.

c) *Food Provisions Unit* (FPU); it provides all services, resources, and supplies regarding nutrition to operation needs and also ensures that operating EHOC personnel have sufficient supplies of food and drinkable water.

5. Administration Section: It provides facility systems and supports the overall physical infrastructure (premises, furniture, equipment, etc.) of the EHOC; The section is divided into the following branches:

a) *Facility Unit* (FU); it organizes building and sectional layout of EHOC units in dedicated, purpose-built facilities, with adequate space for its staff, physically and environmentally secure, accessible, and survivable in the event of a threat or disaster.

b) *Human Resources Unit* (HRU); it formulates job descriptions and classifies staff requirements based on the knowledge, skills, and abilities required for the role and function of each person in the EHOC.

c) *Strategic National Sanitary Stockpile* (SNSS); it develops and deals with the national repository of basic life-support medications (antibiotics, antidotes, etc) and surgical supplies for any nation-wide event of a mass health emergency.

6. Communications/Intelligence Section: The equipment of that sector includes high technology infrastructure (computers, servers, internet stations, software, etc.) and all tools available to support an effective, all-weather-resistant continuous communication and data management according to high-level privacy and security standards. Of utmost importance is the timely, efficient, and accurate information flow on a 24 hour/7 day basis, between the Command section and each of the corresponding field-units from the Operations sector. For that to be accomplished a sophisticated web-based digital tool allowing fast, real-time information sharing to multiple recipients is constantly in function. Some specific sub-functions of that section are:

- A continuous surveillance system, for gathering and exchanging information about sensitive civil national territories (e.g. cities and forest areas), by use of a broad camera-surveillance network and by electronic processing of the data-flow from an advanced, interactive mapping application. The relevant SOPs address all kinds of environmental and man-made threats, monitoring procedures, and actions according to certain hazard thresholds.
- An internet monitoring and medical intelligence/analysis system that verifies information to prevent duplication/ contradictory data collection.
- A rapid early warning/alert system triggering the coordinated rapid recall of staff back to their positions.
- A classified and secure web-based priority system for high-level communication and providing of information among national and transnational decision-makers.

The Communications/Intelligence sector is divided into the following branches:

a) *Data-base Management Unit* (DMU); it controls and centralizes information distribution to appropriate stakeholders for coordinated resource mobilization and correct decision-making to a wide range of emergencies.

b) *Disaster Assessment and Coordination Team* (DACT); it links the abovementioned data with relevant colleagues and experts from both country-level contacts and from the European Monitoring and Information Centre (MIC), as well as from UN/WHO.

c) *Communication Unit* (CU), equipped with telecommunication infrastructure and emergency communication services for sharing urgent relevant information among operational delegates from national and European governmental and private health agencies.

7. Reporting/Briefing Section: Chief is a senior Public Information Officer with pronounced communication skills to prevent inaccurate information spreading and panic diffusion, thus public composure and confidence to be preserved. The chief of the section applies uniform medical reporting SOPs according to the basic requirements: Who – when – where - what and how to report. The Reporting / Briefing section is divided into two branches:

a) *Media and Public Information Team* (MPIT), for regular management of the media and consequently of public expectations for the incident, by the timely transmission of valid information, carefully filtrated for any confidential or higher classified evidence.

b) *Victim Information Team* (VIT); it acts as the liaison between the afflicted population (victims or their families) and state authorities to serve their needs, to manage the list of missing persons, and to provide discreet information, in cooperation with DVIMU and MFCT of the Operations Section. The VIT also formulates antemortem medical records for the deceased and provides forensic support by coordination with local and national law enforcement agencies.

CONCLUSIONS

Albeit the proper function of an EHOC depends on numerous factors, qualifications, and principles, only two ones can be regarded as primary; first, the political will to radically reform the national and trans-national administrative “status quo” at the highest level, so that various authorities to be centralized under the same command through an appropriate legislative framework and second, a properly structured and fully functional organizational plan of an exemplary EHOC.

REVIEW

An overview of the complications of acute and chronic mercury exposures. Past, present, and future

Genica Caragea[1,2], Andreea C. Vãrzaru[1], Oana Avram[2,3], Radu Macovei[2,3], Andreea Costea[4], Dragos M. Popescu[5], Andreea M. Smarandache[3]

Abstract: *Mercury is a chemical element that has been known since prehistoric times and has been used over time as a component of paints, in the treatment of various diseases, and later in various industrial compounds. Mercury enters the body transcutaneously, by inhaling or by ingesting food contaminated with mercury. The most common cause of mercury poisoning is eating seafood, but people can get mercury poisoning from industrial processing, thermometers, dental work, and old paints. The most vulnerable are people at occupational risk due to chronic exposure, as well as fetuses in the intrauterine period. Mercury poisoning produces extremely serious effects on the nervous, renal, and gastrointestinal systems. The nature and extent of mercury poisoning depend on factors such as the route of exposure, the rate of exposure, the distribution and biotransformation of mercury in the body, the chemical form of mercury or the mercury compound. Both mercury in the blood and the urine should not exceed 10 µg/L. The critical values of mercury in the blood are >150 µg/L and the lethal ones exceed 800 µg/L. New diagnostic methods allow the rapid and accurate identification of the concentration of mercury in biological products. Treatment is based on the use of chelating agents. However, the prognosis of mercury poisoning is extremely variable, due to the potentially irreversible nature of the lesions.*

Keywords: *mercury exposure, neurotoxicity, gastrointestinal toxicity, diagnosis, chelation therapy*

INTRODUCTION

Mercury or hydrargyrum (from the Greek language), is one of the 6 liquid elements at a temperature and pressure close to those of the room [1, 2]. It is found in nature in the form of sulfide, also known as cinnabar. Under the name of vermillion, it was used by people to paint the walls of caves in Spain and France in prehistoric times. Archaeological discoveries have shown that mercury has been known since antiquity by the Romans, Greeks, Chinese, and Hindus [3].

Beginning in the 16th century, new information regarding mercury emerged. Agricola detailed the use of mercury and analyzed the effects of inhalation of its vapors on human health [4]. Thanks to the writings of Paracelsus [5], mercury had become, along with antimony [6], an element used in the treatment of venereal diseases [7]. Its anti-inflammatory and antiseptic effects have also determined its use in the treatment of syphilis. It was used in the form of dimethylmercury, but its action on the central nervous system led to the cessation of these treatments [8]. Around

1913, diuretics based on organic mercury compounds were used, which were released on the market for more than 30 years [8]. Mercury is also used in dental work (especially fillings), in some antiseptics, or vaccine preservatives. Mercurochrome was used to treat wounds, later being given up due to not being recognized as safe and effective.

SOURCES OF MERCURY

Mercury is a pollutant of global concern owing to its great toxicity even at very low concentrations [9]. Most of it is deposited in oceanic sediments and soil. The global mercury cycle involves its release from the earth's crust, the air transport of mercury vapor, and its storage in soil and water. Aquatic ecosystems are an essential component of the global biogeochemical cycle of mercury, as inorganic mercury can be converted to toxic methylmercury in these environments [10]. Through burning organic matter and industrial processes, volatile forms of mercury can be released into the atmosphere. The origin of mercury is determined by the type of fuel that was used, such as coal, oil, or municipal waste. Mercury also enters the environment due to the incineration of materials such as car components, batteries, fluorescent bulbs, medical products, thermometers, and thermostats [11]. Leather manufacturing companies or tanneries are highly polluting, generating enormous amounts of solid and liquid waste, including mercury compounds [12].

The most common cause of mercury poisoning is from eating seafood, but people can get mercury poisoning from industrial processing, thermometers, and blood pressure machines, dental work, and old paints [13]. Methylmercury can be absorbed from the water by all sea creatures, but it also continues through the food chain.

Small sea creatures, such as shrimps, often ingest methylmercury and are then eaten by other fish. These fish will now have more methylmercury in them than the original shrimp. This process continues up the food chain, so that a large fish may contain much more mercury than the fish it has eaten.

ROUTES OF PENETRATION

Mercury enters the body transcutaneously, by inhalation, or by ingesting food contaminated with mercury [14]. Transcutaneous absorption of mercury is low. The physical properties of elemental mercury limit its absorption through intact skin. Inhalation of toxic mercury vapors leads to their absorption into the circulatory system, then being distributed throughout the body [15]. The absorbed mercury circulates through the bloodstream, and about half of it is bound to plasma albumin (in association with sulfhydryl groups), while the other half enters the red blood cells and then is rapidly distributed to the tissues; in a few hours, the highest concentration is found in the kidneys. Mercury can build up in the bones, bone marrow, and liver for a short time. One week after exposure, 85-95% of the body's mercury is stored in the kidneys [16].

MERCURY TOXICITY

The primary mechanism of mercury toxicity involves its irreversible inhibition of selenoenzymes, such as thioredoxin reductase (IC50 = 9 nM) [17]. Thioredoxin reductase restores vitamins C and E, as well as several other important antioxidant molecules, back into their reduced forms, enabling them to counteract oxidative damage [18].

Mercury in its various forms is particularly harmful to fetuses as an environmental toxin in pregnancy, as well as to infants. Women who have been exposed to mercury in substantial excess of dietary selenium intakes during pregnancy are at risk of giving birth to children with serious birth defects [19].

The destruction of the proteins that form the glomerular basement membrane leads to the alteration of the renal filtration capacity, with the appearance of severe proteinuria. At the digestive level, mercury destroys the gastric mucosa, a process that favors its absorption in the body. Gastrointestinal symptoms are extremely polymorphic, including digestive hemorrhages, nausea and vomiting, diffuse abdominal pain, and transit disorders, such as constipation or diarrhea [20, 21]. The differential diagnosis should consider other causes of the acute surgical abdomen, such as acute cholecystitis, gastroenteritis, or intestinal occlusion [22-24]. Even less frequent causes such as Amyand hernia or pheochromocytoma may be taken into account [24-26]. Lately, during the COVID-19 pandemic, the SARS-Cov 2 infection has been another cause to be excluded, due to the tropism of the virus for angiotensin convertase (ACE) receptors at the level of the intestinal epithelium [27-29]. A carefully obtained history is necessary to evaluate the risk of mercury poisoning and to avoid unnecessary surgeries in suspected cases. Implementing the principle of safe surgery in the emergency ward is important for a comprehensive evaluation of the patient during admission and to minimize the anesthetic-surgical risk [30].

Mercury poisoning causes some neuropsychiatric, sensory, visual, cognitive, and motor disorders. Previous clinical trials have reported symptoms of tremor, emotional lability, insomnia [31, 32] memory disorders, muscle weakness, muscle atrophy and spasms, headaches, polyneuropathy (paresthesia, hyperactive tendon reflexes, decreased nerve conduction and motor speed), and cognitive impairment [32, 33].

Recent studies found a good correlation between exposure to mercury and other heavy metals and the risk of type 2 diabetes in young adults [34-36]. One possible mechanism is the direct toxic effect of mercury on the beta-pancreatic cells [37].

Toxicity of mercury compounds

There are three different forms of mercury that cause health problems. They are:

- Elemental mercury, also known as liquid mercury or quicksilver;
- Inorganic mercury salts;
- Organic mercury.

The nature and extent of mercury poisoning depend on factors such as the route of exposure, the rate of exposure, the distribution and biotransformation of mercury in the body, the chemical form of mercury or the mercury compound. Organic mercury compounds often produce severe and irreversible toxicity to the nervous system in overdoses, while inorganic compounds produce primary peripheral effects, such as gastroenteritis and renal failure [38-40] (Table 1).

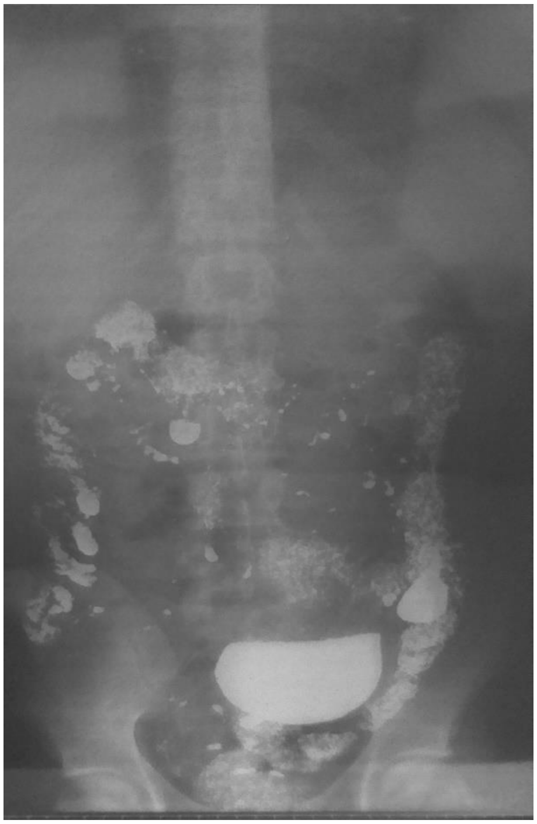
Table 1: Manifestations due to the route of exposure, the rate of exposure, the distribution, and the biotransformation of mercury in the body [34].

	Elemental mercury	Inorganic mercury	Organic mercury
Primary route of exposure	Inhalation	Oral	Oral
Primary tissue distribution	Central Nervous System, Kidney	Kidney	Central Nervous System, Kidney, Liver
Clearance	Renal clearance GI clearance	Renal clearance GI clearance	Methyl: GI Aryl: GI, Renal
Clinical Effects			
Central Nervous System	Tremor	Tremor, Heresy	Paresthesias, ataxias, tremor, dysarthria, tunnel vision
Pulmonary	+++	-	-
GI	+	+++ (caustic)	+
Renal	+	+++ (ATN)	+
Acrodinia	+	++	-
Therapy			
	BAL, succimer	BAL, succimer	Succimer (Early)

GI - gastrointestinal

Quicksilver (liquid metallic mercury) is poorly absorbed by ingestion (Figure 1). Metallic mercury, due to its high volatility and low absorption, has no systemic toxicity. Mercury compounds tend to be much more toxic than the elemental form, and the organic forms are extremely toxic, being involved in kidney and brain destruction. Mercury cyanide can enter the body both by inhalation and by transcutaneous absorption and ingestion. Ingestion of mercury cyanide can cause clinical phenomena similar to both mercury ingestion and cyanide ingestion, leading to extremely severe clinical signs. The degree to which cyanide poisoning occurs is thought to be correlated with the cyanide ions released in the stomach, which depend on the amount ingested, gastric acidity, and volume of gastric contents [41].

Figure 1: Liquid metallic mercury in the large bowel. Source - ICU Toxicology Prof. Macovei collection



Mercury occurs as salts such as mercuric chloride ($HgCl_2$) and mercurous chloride (Hg_2Cl_2), the latter also known as calomel. Because they are more soluble in water, mercuric salts are usually more acutely toxic than mercurous salts. Their higher solubility allows them to be more readily absorbed from the gastrointestinal tract. Mercury salts primarily affect the gastrointestinal tract and the kidneys, and can cause severe kidney damage [20]; however, as they cannot cross the blood-brain barrier easily, these salts inflict little neurological damage without continuous or heavy exposure. Low-grade chronic inorganic mercury poisoning is the basis of acrodynia (pink disease) in children, who typically developed irritability after exposure to mercury-containing teething powder, ointments, and drugs [41-43].

In 1960, JA Freeman of Orange, New Jersey, described the Mad Hatter syndrome, characterized by Danbury-type tremor, found in workers in hat factories [44]. Mercury was inhaled by workers during the textile dyeing process with mercury nitrate. The characteristic symptoms are tooth loss, salivation, neurological deficits described by Ramazzine, the father of occupational medicine, in 1970. One of the most toxic mercury compounds is dimethylmercury. The toxicity is so high that, at doses of a few microliters in contact with the skin, they can cause death.

Methylmercury (MeHg) is the main source of organic mercury. Due to bioaccumulation, it achieves high concentrations found in some species, such as tuna or swordfish [45]. Clinical phenomena occur after a latency varying from a few weeks to a few months after a single exposure [46]. Paresthesias appear as the first manifestation [47], followed later by much more severe manifestations, such as coma. High-level exposure to methylmercury is known as Minamata disease [48, 49].

Another organic mercury compound responsible for human intoxications is ethylmercury, derived from the metabolism of thimerosal (o-carboxyphenyl-thio-ethyl-sodium salt), which is the most widely used form of organic mercury, still being used as a preservative in some human and animal vaccines [50]. The biologic profile is different from methylmercury, with a shorter blood half-life and increased renal elimination [50, 51]. The nervous system affected by intoxication with this substance has the same symptoms as intoxication with methylmercury, adding signs of kidney tissue damage, such as proteinuria, digestive disorders such as nausea, vomiting, and abdominal and dermatological pain [8, 52].

Under the 2013 Minamata Convention on Mercury, organized by the United Nations Environment Program (UNEP), 140 countries have committed themselves to end mercury emissions [53].

LABORATORY DIAGNOSTIC OF MERCURY INTOXICATION

Diagnosis of elemental or inorganic mercury poisoning involves determining the history of exposure, physical findings, and an elevated body burden of mercury. Although whole-blood mercury concentrations are typically less than 6 μg/L, diets rich in fish can result in blood mercury concentrations higher than 200 μg/L [54, 55]; it is not very useful to measure these levels for suspected cases of elemental or inorganic poisoning because of mercury's short half-life in the blood. Free mercury is not well absorbed through the gastrointestinal tract and is excreted almost completely in the feces after ingestion; however, when it persists, mercury volatilizes at room temperature into vapors that are well absorbed by the lungs.

The diagnosis of organic mercury poisoning differs in that whole-blood or hair analyses are more reliable than urinary mercury levels [56].

Both mercury in the blood and the urine should not exceed 10 μg/L. The critical values of mercury in the blood are more than 150 μg/L and the lethal ones exceed 800 μg/L.

Mercury levels in the blood and urine are normally very low. The result of the test, which does not show mercury, indicates that it is likely that the tested person was not exposed to excessive levels of mercury, at least not during the test. Elevated levels of mercury in the blood suggest a relatively recent exposure to mercury. Mercury levels in the blood or urine will not indicate the form or amount of mercury a person has been exposed to.

Blood and urine mercury concentrations are commonly used as biomarkers of mercury exposure. Hair has been used as a biomarker of exposure to methylmercury [57]. Occupational studies show that recent mercury exposure is reflected in blood and urine [54, 58]. A 24-hour urine sample is the most useful in determining the degree of exposure.

The preanalytical phase in determining the species of mercury or total mercury involves a succession of procedures such as sample collection, conservation, and storage, extraction, purification, preconcentration, and separation of species of interest (if applicable).

Exhaustive handling of samples but also the properties of mercury (especially mobility and high volatility) can lead to erroneous results due to either the loss of analyte or contamination of the sample. In addition, interconversion of the species can occur by manipulating the sample. Quantification is usually performed by atomic spectrometry techniques [59].

Some detection techniques that have been used for total Hg analysis are cold vapor atomic fluorescence spectrophotometry (CV-AFS), cold vapor atomic absorption spectroscopy (CV-AAS), graphite furnace atomic absorption spectrophotometry (GF-AAS), cold vapor inductively coupled plasma atomic emission spectrophotometry (CV-ICP-AES), and inductively coupled plasma mass spectrometry (ICP-MS) [60]. Mercury determination through flame atomic absorption spectroscopy (FAAS) gives rise to poor sensitivity [61].

Of all these available methods, cold atomic absorption spectrometry is rapid, sensitive, and accurate, but through this method, the forms of mercury cannot be distinguished. Thin layer and technical gas chromatography are used in the determination of mercury species because with the help of these techniques, the forms of mercury can be distinguished.

Analytical parameters of reviewed research papers about the speciation and determination of mercury by spectrometric instruments (CV-AAS, AAS, AFS, GC-AFS, HPLC-CV-ICPMS, ICP-MS) are presented in Table 2 [60-69].

Table 2: Analytical parameters of reviewed research papers about the speciation and determination of mercury by spectrometric instruments (after Suvarapu LN et al)

No.	Analyte	Detection	Method	Limit of detection	Linearity range	Samples	Ref.
1	Total Hg	CV-AAS	Digestion	3.98×10^{-10} M	2.5–10.0 μg L^{-1}	Biological samples	[61]
2	Total Hg	AAS	Amalgamation	0.2 ng/g for hair 0.02 ng/g for blood	—	Hair Blood	[62]
3	Hg(II)	AFS	Fluorescence optical sensor	9.57×10^{-12} M	2.27×10^{-11} 1.13×10^{-3} M	Hair Urine	[63]
4	MeHg	GC-AFS	SPE	12 ng /g	> 1.5 ng/ mL	Biological samples	[64]
5	MeHg, Hg(II), EtHg	HPLC-CV-ICPMS	Extraction and separation	5.98×0^{-11} (Hg(II)) 2.17×10^{-11} (EtHg) 1.8×10^{-8} (MeHg) M	—	Plasma/serum	[65]
6	Total Hg	ICP-MS	Isotope dilution and UV-photochemical vapor generation	0.5 pg/ g	—	Biological tissues	[66]
7	Hg Total	ETAAS	Extraction of mercury species in toluene	2 mcg/dm^3	-	Blood	[67]
8	Total Hg	GC/MPD	Cleavage with HCl, toluene extraction, addition of Grignard reagent	0.4 mcg/L	-	Blood	[68]

The most powerful tool for the determination of trace elements in a variety of matrices is chemical vapor generation in conjunction with atomic absorption spectroscopy techniques. An absorption technique such as cold vapor atomic absorption spectroscopy (CV-AAS) is one of the most sensitive methods for mercury determination. A reducing agent, stannous chloride ($SnCl_2$), is used to convert ions of Hg_2^+ (aq) in solution to Hg0 (g) which produces a higher analytical absorbance signal. Mercury, having a high vapor pressure, is liberated and entrained in an inert gas of argon after passing through the liquid-gas separator. The Hg vapor is transferred into the optical path of the atomic absorption spectrophotometer where it absorbs light of a specific wavelength at room temperature [60].

Another method of determining mercury is atomic absorption spectrometry (AAS) with graphite furnace atomization, using palladium and magnesium nitrate as modifiers; their use makes it easier to separate the analyzed element from the matrix.

Due to its simplicity and low operating costs, AAS is widely applied in the single-elemental analysis [70, 71]. The samples are exposed to concentrated acids and extended heating, which increase analyte loss. Atomic absorption spectrometry is an analytical method for determining the number of metals or metalloids in a sample, based on the amount of UV or VIS electromagnetic radiation absorbed by the atoms brought into the atomizing state. To establish the atomization temperatures, it is necessary to highlight the interferences that can occur through reaction mechanisms in the graphite furnace. In the case of volatiles, the use of chemical modifiers aims to:

- Shift the value of the atomization temperature outside the non-atomic absorbance that may occur due to the complexity of the matrix, which is especially characteristic of biological samples.
- Obtaining a much higher calcination temperature due to the reduced volatility of the analyte, which allows the elimination of compounds that could give a non-atomic absorbance.
- Increasing the sensitivity of the method by simultaneously atomizing the different forms in which the analyte is present in the matrix.

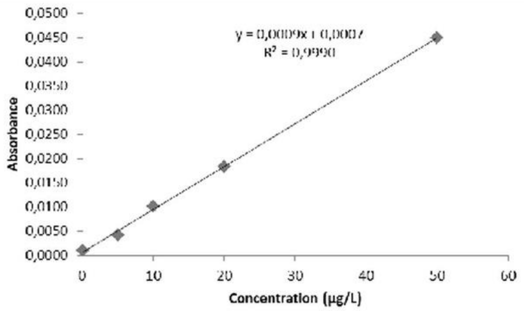
When obtaining optimal operating parameters of the GF-

AAS system, it is desirable to reduce non-atomic absorbance by optimizing drying, calcination, and atomization temperatures and by using the deuterium lamp.

For example, a method for mercury analysis was established by the authors of this paper using a Graphite Furnace Atomic Absorption Spectrophotometer (GF- AAS) Varian SpectraAA-880, with a hollow cathode lamp (Agilent Technologies) and a deuterium lamp (Agilent Technologies) for background correction, coupled to a GTA-100 atomizer and a programmable sample dispenser (Varian, Australia).

The calibration curve was obtained by measuring 5 concentration levels of the standard mercury solution. The results are shown in Figure 2.

Figure 2: The calibration curve used for the determination of mercury



A linear relationship was found between the absorbance at 253.7 nm and the concentration of mercury in the range of 5.0 to 50 µg/L. The representative linear equation was $y = 0.0009\,x + 0.0007$ where: y is the absorbance and x is the mercury concentration (µg/L) calculated by the least-squares method.

The coefficient of determination for the calibration curve was 0.9990 (Figure 2) indicating a good correlation between the absorbance read using the equipment and the concentration of mercury in the standard calibration solution.

The method was applied to the urinary determinations of mercury involved in acute intoxications and to monitor urinary mercury levels during chelation therapy.

However, according to several authors, mercury levels in urine less than 10 mcg/L and bloodless than 20 mcg/L are considered normal. Mercury concentrations in the blood and urine poorly support the neurological clinical findings on electrophysiological measurements. Organic forms of mercury, including phenylmercury, are metabolically transformed into inorganic mercury, compared to methyl- and ethylmercury, which do not undergo metabolic transformations but are eliminated in the bile and feces, so alkylmercury compounds cannot be detected in urine [72].

Urinary elemental mercury levels are useful in assessing acute or chronic mercury vapor poisoning. The concentration of mercury in urine samples in approximately 98% of all evaluated subjects without known mercury exposure is less than 5 µg/L [24].

So, in methyl mercury poisonings, for example, urinary mercury levels do not provide suggestive information, but because methylmercury is concentrated in red blood cells, the whole-blood level may reflect acute methylmercury exposure but does not correlate with the severity of the poisoning/exposure.

THERAPEUTIC OPTIONS

Acute ingestion of mercuric salts can be treated by inducing vomiting or gastric lavage. Resins with polythiol can be administered orally to bind mercury in the gastrointestinal tract. The most effective chelating agents are dimercaprol, succimer, and penicillamine, which have active mono- and dithiol groups.

Acute inorganic mercury poisoning can be treated with dimercaprol in doses not exceeding 24 mg/kg daily, administered intramuscularly in several doses [73]. The treatment is divided into 5-day courses, separated by a few days off. The N-acetylated form of penicillamine is also useful at doses of 30 mg/kg daily in divided doses. Peritoneal dialysis, hemodialysis, and regional extracorporeal hemodialysis with succimer complexation have been used with some success in the treatment of patients with renal impairment [73, 74].

Chelation therapy for acute inorganic mercury poisoning is based on DMSA, 2,3-dimercapto-1-propanesulfonicacid (DMPS), D-penicillamine (DPCN), or dimercaprol (BAL).

Children who ingest mercury can be treated with DMSA. DMSA is the most frequently used agent for severe methylmercury poisoning [75]. When administered orally, it is superior to BAL, DPCN, and DMPS. α-Lipoic acid (ALA) requires correct dosing, as inappropriate dosages increase toxicity. N-acetylcysteine (NAC) as a glutathione precursor is recommended by physicians but has been shown to increase mercury concentrations in the kidneys and the brain.

CONCLUSIONS

Generally, two population groups are more sensitive to the effects of mercury. One of these is fetuses who are most susceptible to developmental effects due to mercury. The second group consists of people who are regularly exposed (chronic exposure) to high levels of mercury (such as populations that rely on subsistence fishing or people who are occupationally exposed). Once the source of mercury poisoning has been identified, the exposure must be discontinued. Novel laboratory methods, such as GF-AAS, allow quick identification of mercury in biological products. However, the prognosis of mercury poisoning is highly variable, depending on the irreversible neurological and organ damage that is present at the moment of diagnosis.

Antibiotherapy: latest current affairs – state of the art 2019

Viorel Ordeanu[1,2], Lucia E. Ionescu[1], Victoria G. Dumitrescu[1], Roxana G. Pricop[1], Răzvan Neagu[1], Diana M. Popescu[1]

Abstract: *Given the continuous growth of the bacterial resistance phenomenon, the appropriate choice of antibiotherapy represents an important step in the treatment and prophylaxis of infectious diseases. Depending on the symptomatology, the dose required for the effective treatment of an infection may vary. Inadequate dosing not only reduces the effectiveness of the antibiotic, but also promotes the emergence of resistant bacterial strains. Also, too high of a dose increases the toxic side effects of antibiotics. Therefore, a personalised antibiotherapy according to: the patient's clinical status, body mass, associated chronic diseases, etc. represents a promising approach in the treatment of infectious diseases.*

The purpose of this study is to present the most important current affairs regarding the emergence of new antibiotics, the maximum doses recommended by the latest version of the "European Committee on Antimicrobial Susceptibility Testing" (EUCAST - version 9/2019) and providing an indication on whether these antibiotics are used in Romania.

Keywords: *antibiotics, antibiotherapy, maximum recommended dose, antimicrobial chemotherapics*

INTRODUCTION

Antibacterial chemotherapics (antibiotics) have become the emblematic drugs of the 20th century starting with the first antibacterial chemotherapic, Salvarsan (invented by Paul Ehrlich, of German origin, in 1909) and the beta-lactamase Penicillin (discovered by the American Alexander Fleming, in 1929). Currently, there are hundreds of antibacterial antibiotics (AB), of which 269 have been approved for antibiotherapy (ABT). It was believed that bacterial diseases could be eradicated, but the practice has shown since the middle of the last century that the phenomenon of bacterial resistance to antibiotics emerges, that much higher doses are now needed, with modified conditioning and dosage, targeted use, in phases and combined or associated, even the use of new antibiotics, as far as they can be produced [1-7].

ANTIBIOTHERAPY

Over time, the efficacy of ABT has been reduced, despite advances in medicine in general and pharmacology in particular. Resistant, multi-resistant and all-resistant bacteria create the most serious problems in medical practice and more and more patients die from infections or over-infections that do not respond to treatment. This worrying phenomenon has been thoroughly investigated, starting with the application manner of ABT. Thus, the website www.longitudeprize.org published in 2014 an international medical statistic [6] having as results the inappropriate use and prescription of ABs:

- 90% of the physicians prescribed AB under the pressure of the patient who wanted a certain AB (namely, "Customers is King?!");
- 70% of the physicians prescribed AB without being sure

[1] Military Medical Research Center, Bucharest, Romania
[2] "Titu Maiorescu" University, Bucharest, Romania

Corresponding author: Ionescu Lucia
ionescu.lucia@gmail.com

that the etiology of the disease is bacterial or viral;

• 49% of the physicians prescribed AB for a week or more, without a prolonged treatment being needed;

•44% of the physicians prescribed AB only preventively, after discharge from surgery.

Following the highlight of the multiple factors that lead to the irrational use of ABs, medical and especially non-medical, in 2017 UN/WHO launched a new conception on prophylaxis and treatment – One health – and officially formulated recommendations for the Member States, with the goal of maintaining the efficiency of ABT worldwide. Based on these recommendations, each country sets its own research directions for medical and pharmaceutical scientific research. In this respect, a prize was established worldwide, Longitude Prize (2014). It has a prize pool of £ 10m to reward a competitor who will develop a test targeted on the rapid diagnosis of the diseases that require ABT. Through the rational use of ABs, the test would lead to the conservation of efficiency and shall revolutionise healthcare worldwide. The test should be accurate, fast, inexpensive, easy-to-use and accessible to anyone, anywhere in the world. By this test, shall be identified which ABs are needed and which shall be used. But these requirements seem utopian in the current stage of development of science and technology, it being unlikely to discover something that corresponds at least partially. Therefore, the prize has not been awarded so far.

Inventing new ABs is costly and difficult. These must meet divergent conditions: high toxicity for microorganisms (thus, antimicrobial efficacy), but little or no toxicity for the treated macroorganism; also, it must not have significant side effects; it must be produced industrially with reasonable costs; it must be stored and managed conveniently etc.

For the in vitro evaluation of the antibacterial effect of the AB, the Minimum Inhibitory Concentration (MIC) testing is performed on the respective bacterium (Breakpoint by determination in microdilutions in liquid culture medium) and the Kirby-Bauer diffusimetric antibiogram (ABG) with the measurement of the diameter of the Inhibition Zone (IZ) on the solid culture medium [2, 7]. One can choose from theoretically efficient ABs [1, 3, 4, 5] those that inhibit isolated and identified bacteria from the patient, by interpreting in the SIR system (Susceptible, Intermediate and Resistant) the diameter measured in millimeters, compared to EUCAST tables [2]. Because often the result obtained in vitro was between susceptible and resistant, this is noted as intermediate and for clinicians it was equivalent to resistant, because it would not have the desired therapeutic effect. In the current conditions of spread of the bacterial resistance phenomenon towards antibiotics, it is recommended to increase the dose of ABs, where the pharmacological properties allow, so that the bacteria pass from the intermediate to the susceptible area. By this approach of bacterial susceptibility, the intermediate bacteria pass from the resistant group to the susceptible group, and the SIR system gains another significance. The paraclinical findings become a practical indicator for the guidance of the clinician:
S = susceptible to standard dosing regimen (usual dosage)
I = intermediate, susceptible to high exposure (high doses, where possible)
R = resistant (therefore, useless for use).

As a result, the most handy method of combating bacterial resistance is the justified increase of the consumption of ABs, by increasing the single dose, daily or per cure, the frequency of administration or the duration of treatment, where the pharmacological characteristics allow (for example, in order not reach the toxic dose). The maximum recommended doses can be per dose, per day or per cure, and the cure can be short (1-5 days), medium (5-10 days), long (10-15 days) or very long (15-60 days). The doses are approximated depending on the conditioning of the drug (single antibiotic package or fixed combination), as well as the body mass of the patient. Any drug is theoretically dosed for an average patient, with a net body weight of 70 kg; so for a patient over 140 kg it should be double dose and for one below 35 kg it should be half dose. Some drugs, including ABs, are given by calculating in mg/kg body weight, especially in paediatrics, where children may have very different weights. When choosing ABs and in determining the dose, one must take into account, in addition to the pharmacological criteria imposed by antibiotherapy (which are well known), also: the general and particular contraindications, the age, the general patient status, the associated diseases, possible allergies or intolerances, the need for combinations with anti-beta lactamases or combinations with ABs or other anti-infective or adjuvant drugs. Consideration should also be given to possible antagonisms, inactivation with drugs and food, unwanted adverse or secondary phenomena as well as possible Herxheimer-type reactions. All this leads to a bi-unequivocal personalized ABT: depending on the needs and characteristics of the patient as well as the susceptibility of the pathogenic bacterium [8-13].

THE CLASSIC RECOMMENDATIONS

Professor Balş, the professional owner of the hospital that bears his name formulated the basic principles of antibiotherapy (also called antibiotic therapy) regarding: indications, contraindications, errors, associations of ABs, which are still valid today. These principles have been applied in Romanian medical practice by Prof. Angelescu and his students, with undeniable successes. But at present, although all these principles have remained valid, their effectiveness in ABT practice is progressively diminished, due to the the spread of bacterial resistance to ABs, worldwide. As a result, we must complement these principles with new observations and discoveries in order to maintain the effectiveness of ABT. The most important news for ABT are not the new ABs, but the increased doses of those already known and their grouping by type of bacterial resistance.

MAXIMUM DOSES CURRENTLY RECOMMENDED

The new maximum doses are recommended by EUCAST 2019, p.96-99, systematized on AB groups, International Common Names (DCI) and with mentions for different clinical situations (2), and in the following we shall provide a summary, with the mention, „*" If used in Romania:

Penicillins: Benzylpenicillin* 1.2 g (2MU) x 4-6 iv, or 2.4 (4 MU) x 6 iv in meningitis and pneumonia; Ampicillin* 2 g x 4 iv, or 2 g x 6 iv in meningitis; Ampicillin+Sulbactam* 3 g x 4 iv; Amoxicllin* iv 2 g x 6 iv; Amoxicllin - oral 1 g x 3; Amoxicllin+clavulanic acid* iv 2.2 g x 3 iv; Amoxicllin+ clavulanic acid - oral 1 g x 3; Piperacillin* 4 g x 4 iv; Piperacillin+tazobactam* 4.5 x 4 iv; Ticarcillin* 3 g x 6 iv; Ticarcillin+clavulanic acid* 3.1 g x 6 iv; Phenoxymethyl-penicillin 2 g x 4 oral; Oxacillin* 1 g x 6 iv; Cloxacillin 1 g x 4 oral or 2 g x 6 iv; Dicloxacillin 2 g x 4 oral or 2 g x 6 iv; Flucloxacillin* 1 g x 4 oral or 2 g x 6 iv; Mecillinam 0.4 g x 3 oral.

Cephalosporins: Cefaclor* 0.25-1 g tidpo; Cefadroxil* 0.5-1 g bidpo; Cephalexin* 0.25-1 g bid-tid po; Cefazolin* 1 g tid-qid (or 2 g tid) iv; Cefepime* 2 g tid iv; Cefixime* 0.2- 0.4 g bid po, or 0.4 g po in gonorrhea; Cefotaxime* 2 g tid iv, or 2 g qid in meningitis; Cefpodoxime* 0.1-0.2 g bid po; Ceftaroline* 0.6 g tid iv (slow infusion – 2 hrs); Ceftazidime* 2 g tid iv or 1 g x 6 iv; Ceftazidime+avibactam* 2.5 g tidpev (2 hr infusion); Ceftibuten 0.4 g po; Ceftobiprole 0.5 g tid iv (slow infusion – 2 hrs); Ceftolozane+tazobactam* 1.5 g tid iv (slow infusion – 1 hr); Ceftriaxone* 2 g bid iv, or 4 g iv in meningitis; Cefuroxime* 1.5 g tid iv; Cefuroxime 0.5 g bid po.

Carbapenems: Ertapenem* 1 g x 1 iv; Imipenem* 1 g qid iv (30 mins perfusion); Meropenem* 2 g tid iv (3 hrs perfusion), or in meningitis 2 g tid iv; Meropenem+vaborbactam 4 g tid iv.

Monobactams: Aztreonam 2 g qid iv.

Fluoroquinolones: Ciprofloxacin* 0.75 g bid po, or 0.4 g tid iv; Levofloxacin* 0.5g bid po, or 0.5g bid iv; Moxifloxacin* 0.4g x 1 po, or 0.4g x 1 iv; Norfloxacin* 0.4g bid po; Ofloxacin* 0.4 g bid po, or 0.4 g bid iv.

Aminoglycosides: Amikacin* 30 mg/kg x 1 iv; Gentamicin* 7 mg/kg x 1 iv; Netilmycin* 7 mg/kg x 1 iv; Tobramycin* 7 mg/kg x 1 iv.

Glycopeptides and glycolipopeptides: Dalbavancin* 1 g x 1 iv; Oritavancin 1.2 g x 1 iv; Teicoplanin* 0.8 g x1 iv (single dose in slow infusion – 3 hrs); Telavancin 10 mg/kg x 1 (slow infusion – 1 hr); Vancomycin* 0.5 g qid iv, or 1 g bid iv, or 2 g x 1 in perfusion.

Macrolides, lincosamides and streptogramins: Azithromycin* 0.5 g x 1 po, or 0.5 g x 1 iv, or 2 g po in single dose; Clarithromycin* 0.5 g bid po; Erythromycin* 1 g qid, or 1 g qid iv; Roxithromycin 0.15 g bid po, Telithromycin 0.8 g x 1 oral; Clindamycin* 0.3 g qid po, or 0.9 g tid iv; Quinupristin+dalfopristin 7.5 mg/kg tid iv.

Tetracyclines: Doxycycline* 0.2 g x 1 po; Eravacycline 1 mg/kg bid iv; Minocycline* 0.1 g bid po; Tetracycline* 0.5 g qid po; Tigecycline*0.1 g followed by 50 mg bid iv.

Oxazolidinone: Linezolid* 0.6 g bid po, or 0.6 g bid iv; Tedizolid* 0.2 g x 1 po.

Other antibiotics: Chloramphenicol* 2 g qid po, or 2 g qid iv; Colistin* 4.5 MU bid iv; Daptomycin* 6 mg/kg x 1 iv; Fosfomycin* 8 g tid iv or 3 g x 1 po in a single dose; Fusidic acid* 0.5 g tid iv; Metronidazole* 0.5 g tid po, or 0.5 g tid iv; Nitrofurantoin* 50-100 mg tid-qid po; Nitroxoline* 0.25 g tid po; Rifampicin* 0.6 g bid po, or 0.6 g bid iv; Spectinomycin 2 g x 1 im; Trimethoprim 0.16 g bid po; Trimethoprim+ sulfamethoxazole* 1.44 g bid po, or 1.44 g bid iv.

CLINICAL GROUPING OF ABs

Changing the posology and increasing the doses of ABs, where necessary and possible, contributes to maintaining a reasonable susceptibility of pathogenic bacteria, maintaining the efficiency of ABT. Clinicians should rationally use ABs and shall apply, where appropriate, the new recommendations, which move the category of bacteria with intermediate sensitivity, from resistant to susceptible [2]. Consideration should also be given to the recent clinical classification of ABs in the three groups: for infections with common bacteria (Access group antibiotics), with resistant bacteria (Watch group antibiotics) and the reserve (Reserve group antibiotics), as well as special antibiotics (eg anti-tuberculosis, anti-leprosy), according to the WHO Model List Essential Medicines, no 20/2017 and 21/2019 [1]. The practical advantage for medicine is immense, but if in medical practice it is found that many clinicians still do not follow the rules of good practice of ABT, action will have to be taken. One of them could be, in extremis, that according to the recommendations of WHO 2017 and 2019, ABs from the therapeutic groups should be prescribed according to the competence of the doctor:

ABs group I, usual, by any doctor with the right to free practice,

ABs group II, for resistant or multidrug-resistant bacteria, by specialized clinicians,

ABs group III, reserved, by primary care clinicians,

Special ABs, by the clinicians, according to their specialty.

Obviously, "off-label prescriptions" could represent the exception, in justified cases; As an example, it has been found that the antiparasitic Metronidazole is also the most effective antianaerobic AB.

There are also some ABs, which, although authorized, are so little used in national medical practice that they could be considered as new ABs. It is interesting to see how many new ABs will be authorized in the coming years. It is very important to discover new anti-infective drugs, both with new molecules, and by highlighting antibacterial and/or antibiofilm properties in pharmaceuticals known for other pharmacological effects. This type of applied research involves smaller investments, and the results can be faster, going up to the patenting of new innovative anti-infective drugs, in the near future.

CONCLUSIONS

Antibiotherapy is constantly dynamic, in order to keep up with the adaptation of pathogenic bacteria to the selection of pressure exerted by ABs, We must be aware of these trends, apply new acquisitions in the field of drugs, dosage conditioning and dosage, to help maintain an effective ABT, and abandon, where appropriate, the old methods and habits. Unfortunately, it is possible that some healthcare workers may continue to prescribe ABs, not for treating the patient, but for their own peace of mind and as well as their patients' or for any other reasons.

A practical approach of the pediatric patient with obstetrical brachial plexus palsy starting from 28 cases – Single-center experience over 6 years

Alice Dica[1], Diana Barca[1,2], Oana Tarta-Arsene[1,2], Ioana Minciu[1,2], Catrinel Iliescu[1,2], Carmen Burloiu[1], Niculina Butoianu[1,2], Magdalena Budisteanu[1,3,4], Cristina Pomeran[1,2], Carmen Sandu[1,2], Ligia Robanescu[1], Cristina Anghelescu[1], Dragos Zamfirescu[5], Gabriela Musat[6,7], Ovidiu Musat[8], Dana Craiu[1,2]

Abstract: *Neonatal brachial plexus palsy is a complication that occurs during difficult vaginal delivery or due to unexplained causes, probably prenatal in which some or all brachial plexus branches are affected (avulsion, rupture, stretching). A cohort of 28 cases evaluated in our clinic in 6 years and 6 months (Jan 2007-July 2013) from the clinical and paraclinical point of view, treatment, and the outcome were analyzed. 17 (60.7%) of the patients were boys and 11 (39.2%) were girls. 14 (50%) had right brachial plexus palsy, 12 (42.8%) had left brachial plexus palsy and 2 (7.1%) had bilateral involvement. 5 (17.8%) of them had reconstructive surgery done. 11 (39.2%) had good to complete recovery. The purpose of this paper is to underline the importance of early presentation for neurological evaluation and the beginning of physical therapy.*

Keywords: *brachial plexus palsy, physical therapy, reconstructive surgery of brachial plexus*

INTRODUCTION

Neonatal brachial plexus palsy (NBPP) – is a functional disturbance due to brachial plexus injury, characterized by deficits in the areas served by the brachial plexus branches (C5 to T1). The following NBPP types have been described according to the lesion's level: total (C5 to T1) or partial – superior (C5 to C6), middle (C5 to C7), inferior (C8 to T1). The name of this dysfunction is controversial, some authors calling it obstetrical, because the trauma during a difficult delivery is the most common cause, while others name it congenital including obstetrical and unexplained cases due to a prenatal cause. In these circumstances, an umbrella term will be NBPP [2, 3, 6, 9]. Some or all the fibers of the brachial plexus branches suffer stretching, rupture or avulsion. The incidence is 0.1 - 0.4% of live births and has remained relatively constant over time [3, 6, 7, 9]. A multidisciplinary approach and consensus are needed for a better outcome.

OBJECTIVES

This paper aims to analyze the cohort of patients with NBPP followed in the Pediatric Neurology Department, to highlight the variability of NBPP symptoms at presentation, to identify and correlate specific items related to clinical signs, investigations, and outcome, and to establish a protocol of diagnosis and follow-up for children with NBPP, according to the international recommendations adapted to the local needs. We propose a treatment algorithm, allowing optimum outcomes for these children.

MATERIALS & METHOD

The archive of the Pediatric Neurology Clinic was retrospectively analyzed over 6.5 years (January 2007 – July 2013), selecting the patients with NBPP. Approval from the Local Ethics Committee was obtained. Narakas's classification was used at the first admission to diagnose the NBPP type: superior, middle, inferior, and total [7]. The clinical status was registered at different times: at presentation, at 3, 6, 12 months follow-up. Active motor scale [1, 2, 4, 8, 9], Toronto score [1, 2, 4, 8, 9], and protocol for obstetrical brachial plexus palsy (Hospital for Sick Children Seattle) [8] were retrospectively applied, using registered neurological examinations, reports of physical therapy specialist, from files. Laboratory findings, EMG and nerve conduction velocities of the upper limb and brachial plexus MRI (performed if needed), treatment choices, and their results were also evaluated [10]. We designed a separate questionnaire for present status evaluation, including data about active movements, strength, trophic changes summarized in a score. The prognosis was quantified as follows: score 0-12 – poor recovery, score 13-24 – moderate recovery, 25-36 – good recovery, or complete remission. Statistical analysis used the SPSS17 program.

RESULTS

28 patients with the diagnosis of NBPP were identified between January 2007 – July 2013.

Evaluation schedule. All patients came at 3 months for neurological evaluation; 23 children (82.1%) returned for reevaluation at 6 months, and only 10 (35.7%) at 12 months.

History and clinical data. Among them, 17 were boys (60.7%) and 11 girls (39.3%), 4 days to 13 years old at admission. 14 (50%) cases had the right side, 12 (42,8%) had left side, and 2 (7.1%) had bilateral brachial plexus involvement. 6 (21.4%) of the cases have total NBPP and 22 (78.6%) – partial – superior (C5-C6) or extended superior (C5-C7) NBPP. All the children were born spontaneously, 13 (46.4%) of them had > 4000 g, another 8 (28.5%) had birth weight > 3900 g and eight (28.5%) patients had 2800 – 3900 g, but with difficult labor and delivery. Four patients (14.2%) had Claude Bernard Horner syndrome (CBH) and 3 (10.7%) had further associated pathology – global developmental delay, diplegia, microcephaly in evolution. 13 patients (46.4%) were first evaluated in our clinic in the first month of life, 12 (42.8%) between 1 and 3 months, 2 (7.1%) between and 1 (3.5%) after 6 months. 2 (7.1%) mothers had prenatal hypertension and hypertension during pregnancy, but that didn't affect the children.

Investigations. 6 patients (21.4%) had electrophysiological studies (EMG and nerve conduction velocities) performed in the first 2 months of life, in 3 cases (10.7%) repeated at 3 months and in 5 (17.8%) after 6 months. 6 patients were evaluated with MRI of the cervicobrachial region. 3 (10,7%) of them had avulsion (preganglionic lesions, usually associate pseudomeningoceles), 1(3.5%) had rupture (usually are postganglionic lesions, could associate pseudomeningoceles) and 2 (7.1%) had stretching/ elongation (postganglionic lesions, neuroma or hematoma or diffuse lesions). 4 (14.2%) of the children who had brachial plexus surgery had pre- and postganglionic lesions and 1 (3.5%) had postganglionic lesions.

Treatment. All patients received physical therapy, Vojta method (in our clinic); among them, two patients (7.1%) had already started physiotherapy through the Bobath method (in another Clinic). 12 patients (42.8%) were included in an intensive physical therapy program and 16 (57.1%) received inconstant or for a short period physical therapy. Good recovery was registered in 6 patients (21.4%) who performed intensive physical therapy and 5 patients (17.8%) among those with inconsistent therapy. Five patients (17.8%) had surgical reconstruction of the brachial plexus, 3 (10.7%) of them had total brachial plexus palsy and two (7.1%) had extended superior brachial plexus palsy.

Follow-up. Evolution at 3 month after physical therapy, evaluated with Toronto score (T score) showed score > 3.5 in five patients (17.8%) and values < 3.5 in 23 patients (82.1%). From the 23 patients (82.1%) with T score < 3.5, 6 (21.4%) were evaluated for surgical procedure and five (17.8%) were operated, in one (3.5%) case it was not necessary. The rest continued physical therapy. 18 patients (64.2%) with a T score <3.5 were not evaluated for surgery because they did not come for their scheduled evaluation/ follow-up.

Outcome. Eight (28.5%) patients had a poor recovery, 9 (32.1%) patients had a moderate recovery, 11 children (39.2%) had good recovery, among them 6 (21.4%) with complete remission. All of the children with good recovery to complete remission had superior or extended superior

NBPP.

DISCUSSIONS

Most of the children (18 – 64.2%) did not comply with the follow-up schedule. That is because they recovered with physiotherapy or spontaneously or because they were lost to follow-up. The last evaluation, consisting of a questionnaire applied on the phone showed that the majority had a good outcome, most probably because most of the cases were mild, superior type, and a good response to therapy (even those who have made physical therapy at home with their parents). Besides, we could not compare the types of reconstructive surgery, because the number of children undergoing surgery was too small (5). Among them, 4 children had reconstruction of the brachial plexus, and for one patient neurotomy was performed (the fibrous sleeve around the brachial plexus was removed).

Legend:

* Toronto Score - elbow flexion 0-2, elbow extension 0-2, wrist extension 0-2, thumb extension 0-2, fingers extension 0-2;

**Cookie test - capacity of holding a toy in the hand and put it on his mouth , elbow flexion/extension;

*** Surgery - optimal age for surgery in C5-C7 lesions is 6-7 months, optimal age for surgery in C5-T1 lesions +/-Horner's syndrome is <6 months (ideal 3-4 months).

Age at first presentation in NBPP is of paramount importance for the subsequent treatment choice. It is important that the children with BPP to be early referred – even from birth for evaluation and treatment, in this way – T score at age 3 months will be the most valuable tool for an indication of early surgery if needed.

Cervico-brachial MRI was performed only in some of the patients with a T score <3.5. The importance of MRI is high for the treatment choice – in case of the complete avulsion, surgery is indicated.

Although some studies report 80-90% of the good recovery in unilateral, superior brachial plexus palsy, in our cohort we had only 11 (39.2%) patients with good recovery, probably due to inconsistent physical therapy and non-compliance to scheduled evaluations.

The results cannot be applied in the general population due to the small number of patients analyzed. A larger, prospective study is needed in the future to fill in the gaps. To be noted the good clinical practice of neonatology specialists, pediatricians, and general practitioners who evaluate the children in the first days of life and immediately take action, sending them immediately to pediatric neurology for evaluation and treatment.

– the age of first neurological evaluation and initiation of physical therapy decreased and the number of evaluated children with NBPP increased in the last few years in Romania although this is purely based on anecdotal data as no national registry exists for NBPP. That is why we strongly agree that the first protocol of diagnosis and treatment was needed in our country (Figure 1). Of course, that the experience of the next few years and the discoveries in the field will help us to permanently improve the protocol for better practice, according to the international rules.

CONCLUSIONS

The use of protocols for diagnosis and follow-up makes us „speak the same language”, have the same criteria for diagnosis, evaluation, and treatment, with some particular situations due to the local needs.

Early diagnosis and treatment are important because the outcome is better – than raises the quality of life of these patients and the addressability for physical therapy. Vojta therapy has good results in NBPP. Better information of the patients concerning the steps of evaluation of NBPP and the importance of compliance with the protocol is critical for a better outcome and for avoiding a permanent deficit.

Reconstructive surgery must be done in selected cases for a better recovery.

This is a pilot study, with a proposal of protocol for diagnosis and treatment, according to the international protocols in force, but larger, prospective studies are mandatory to complete and refresh the existing data (Figure 1).

Aptamer as a proper alternative instead of monoclonal antibody in diagnosis and neutralization of menacing biological agents

Hadi E.G. Ghaleh[1], **Mojtaba Sharti**[1], **Mohammad S. Hashemzadeh**[1]

Abstract: *Of the major threats to contemporary mankind, is the use of very dangerous and lethal biological agents as the biological weapons. The first step in confronting with this serious threat after prevention, is the accurate and rapid detection of this agents and neutralization of them. In this article, the role of molecules known as aptamer, has been studied in biological defense against these menacing biological agents. Traditional methods for detection of these agents are based primarily on immuno-affinity assays and the use of antibody molecules. While the modern methods, based on aptamer-affinity assays, are being replaced with traditional methods, due to the abundant advantages of them. The selection and preparation method of specific aptamer with high binding affinity to these biological agents is known as SELEX and the use of magnetic nanoparticles to perform this procedure (Mag-SELEX) is very common. The isolated aptamers with high specificity can also be used in neutralization and inhibition of menacing agents function, in addition to, quick and accurate diagnosis of these agents, utilizing them in nano-biosensors, based on aptamers (as the nano-aptasensors).*

Keywords: *Aptamer, SELEX, nano aptasensor, diagnosis and neutralization, menacing biological agents*

INTRODUCTION

Nowadays virulent and dangerous biological agents which can be used as biological weapons are becoming a considerable threat to us [1]. Some of very important agents used in bioterrorism are namely botulinum neurotoxins which are some of the strongest toxins known to men and produced by the anaerobic bacteria called clostridium botulinum [2]. Botulinum neurotoxins, especially three types of A, B and E, have been known as dangerous biologic weapons. Among these three serotypes, serotype A is more potentially virulent [3]. The first action against these very dangerous biological agents, after prevention is to identify and detect the agent accurately and rapidly and then to neutralize it [4]. Modern methods of identification and neutralization is based on molecules called aptamer [5]. In this article we will first introduce aptamer and chemical modifications possible to make on this molecule to approach certain purposes, and compare them to antibody molecules as a conventional tool in diagnoses and neutralization of the biological and viral agents or their exclusive products (such as toxins and etc.) and we will interpret concisely the works done around the world.

APTAMER, AS A NEW MOLECULAR DEVICE

Aptamer is generated from the Latin word of "Aptus" which means "to fit". In fact, aptamers are oligopeptides or single stranded oligonucleotides (DNA or RNA) with high affinity for binding to target molecule (Figure 1). They create a bond with high specificity through their third structure to a target molecule [6]. In this article we discuss about oligonucleotide aptamers, especially DNA aptamers. By development of

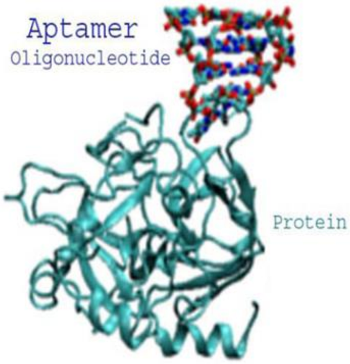
Corresponding author: Mohammad S. Hashemzadeh PhD
Dr_Hashemzadeh@bmsu.ac.ir

molecular sciences and setting up the SELEX technique, the specific DNA/RNA aptamers have been separated for binding to many molecules. These molecules are consisted of nucleic acids, amino acids, sugars and their polymers, and also mineral compounds, enzymes, growth factors, antibodies, the molecules binding to cells, chitins and even viral components [7].

Figure 1. A schematic representation of the binding of aptamer molecule to the target protein



Natural aptamers in living systems

Naturally, aptamer is found in bacteria, archaea bacteria, fungi and plants, and acts as a part of riboswitch structures and often plays a role in regulation of expression of the genes involved in production of vitamins (co-enzymes) and in some cases is efficient in regulation of amino acids' production [8].

Evolution of aptamers in non-living systems

In 1990, Gold and Tuerk attained RNA fragments which were able to bind to T4 bacteriophage DNA polymerase. These oligonucleotide fragments were selected by a new combinatory technique called SELEX (systematic evolution of ligands by exponential enrichment). The meaning of this expression is that among a collection of aptamers with various sequences, it is possible to attain the specific sequence with high binding affinity to target molecule through some screening steps [9].

Aptamer library (AptLib)

The initial library for performing the SELEX process includes single stranded DNA (or RNA) oligonucleotides with a central core (approximately 40 bases) containing random and variable sequences (more than 1,015 different fragments), in which every oligonucleotide is consisted of certain flanking sites in both ends that are fixed positions for primer attachment [10]. In the middle of these constant regions (i.e. the central core), sequences of 15 to 75 (e.g. 40) nucleotides are randomly situated and every four base (A, G, C, T) may be situated in that position with the same probability [11]. These fragments are prepared by frequent synthetizations, with mixture of four types of nucleotides, coincidentally and by synthetization machine (will extendedly be discussed in results and discussion section) [12].

Aptamer library screening by SELEX cycles

In this stage, fragments with the highest affinity and specificity for target protein is selected from the aptamer library, through several SELEX cycles (usually 13-15 cycles). Repetition of these cycles is required for attaining the suitable affinity [13].

Using magnetic nano-particles for screening by SELEX cycles (Mag-SELEX)

Some of Mag-SELEX benefits include:
1) No requirement for special facilities or equipment,
2) Easiness of gathering and separation of aptamers by SELEX process only using a magnet or a simple centrifugation,
3) Possibility of using nano particles for two purposes: stabilization of target protein and also making aptamers single stranded in each cycle,
4) Possibility of performing the methods such as flow cytometry for evaluation of affinity,
5) Needing to little amount of protein in this technique (around 100 micrograms),
6) Possibility of coating nano particles with streptavidin for very strong interaction with biotin and thus prevention of wastage of stabilized protein during the washing process in which the conditions becomes tougher by rising cycle number of SELEX,
7) Expansion of protein contact surface with existent aptamers in the solution and rise in SELEX efficiency and abate of errors,
8) Easiness of stabilizing protein on these Nano particles.

It is worth mentioning that the main procedure of SELEX in different methods such as cell SELEX, CE SELEX, microfluidic SELEX (M-SELEX) and etc. are the same [14-16].

Corrections and chemical rearrangements of aptamer molecules

For increasing the stability and resistance of these molecules in clinical use, labeling or increasing the performance of these molecules, some modifications are made on these aptamer oligonucleotides.

The most important modifications include:

1) Corrections on carbon 2' of sugar including: a) Adding fluorine and amino group to pyrimidine bases. b) Adding hydroxyl group to purine bases. c) Adding o-methyl group to purine and pyrimidine bases. In clinical applications, 2'-O-

methyl oligomers are in priority, for they are less toxic than other corrections on carbon 2' (these structures exist naturally in ribosomal RNAs) [17].

2) Capping of 3'-terminus of oligonucleotide including: a) Attachment of inverted thymidine (3'-idT) to 3'-end of oligonucleotide and creation of 3'-3' connection. b) Attachment of biotin to the 3'-end [18]. 3) Capping of 5'-terminus of oligonucleotide including: a) Adding alkyl-amine group to 5'-end phosphate. b) Attachment of 5'-end of oligonucleotide to polyethylene glycol or on surface of liposome. c) Adding cholesterol, fatty acids and protein [19]. 4) Correction and chemical rearrangement of phosphate group which means replacement of sulfur group instead of the oxygen that doesn't attend in phosphodiester bond (thio-aptamer). 5) Adding signal peptides to aptamers such as penetrating peptides including Tat and antennapedia and fusogenic peptides [20]. 6) Labeling aptamers with fluorescent molecules (for example derivatives of fluorescein such as FITC, FAM and etc.) for flow cytometry or with biotin molecules for stabilizing aptamer on solid surface coated with streptavidin (for performing ELISA or in biosensors design) [21].

It's rarely seen that the corrections and chemical rearrangements made for resistance improvement are effective on the main features, such as binding affinity and third structure. That's while in performance most of these modifications are possible in primary library before SELEX [22].

Comparison of aptamers with antibody molecules

1) Antibodies' half-life is limited, while aptamers are very stable despite of the chemical rearrangements of their nucleotides. 2) Antibodies unlike aptamers are sensitive to environmental conditions such as temperature, pH and etc. 3) Antibodies have irreversible denaturation, that's while aptamers have denaturation and renaturation capacity because of their nucleic acid structure. 4) Antibodies unlike aptamers are immunogenic and this causes their rapid elimination in the body in clinical applications. 5) Size of antibodies unlike aptamers is massive (around 150 KDa) which causes long-term pause of them in blood and slow penetration in tissues and as a result, causes bone marrow toxicity in radioactive form [23]. 6) The procedure of antibody production is very difficult and for aptamers it is only difficult in the first time, during the panning steps of SELEX and then by sequencing of the aptamer selected from library, it is possible to synthesize the sequence attained easily. 7) Possibility of using aptamers in the chips that are based on DNA, so that in protein staining process aptamers do not get color. 8) Impossibility of antibody production for little non-immunogenic molecules; and possibility of aptamer production regarding to these molecules. 9) Factors like pH variation, salt concentration, heat, and chelating agents may help the process of aptamer reactivation and creation of functional structures in them. But for antibodies these agents would cause denaturation of them. 10) Stabilization of aptamers and labeling them are easier than antibodies.

These prominences have caused them to be widely used as molecular detectors in biosensors based on aptamer molecules (apta-sensors) and nanobiosensors based on aptamer molecules (nano-apta-sensors) [24].

AN OVERVIEW OF THE RESEARCH WORKS DONE UNTIL NOW, IN RELATION TO APTAMERS AND THEIR APPLICATIONS

Selection of aptamers for binding to antibodies, proteins and growth factors

- In 1996, Wiegand et al. succeeded in isolating aptamers) single stranded DNA and also RNA with 2'-amino chemical arrangement) against human IgE to inhibit the interaction of this molecule with "FcεRI" receptor on surface of basophilic leukemia cells of rat (as a new drug for the treatment of allergic diseases) [25].

- In 1995, Doudna et al. succeeded in selecting a RNA aptamer to detect the main epitope of insulin receptor antigen on surface of human cells [26].

- In 1995, Geling et al. selected RNA aptamers (with 2'-amino chemical arrangement) to inhibit the activity of fibroblast growth factor [27].

- In 2002, Lupold et al. isolated the RNA aptamer detecting prostate specific membrane antigen (PSMA) on surface of prostate cancer cells and labeled that aptamer by fluorescent molecules to observe its ligand-binding function in condition of "in vivo" [28].

Disruption of translation pathway signs of lymphocytes by Aptamar

- In 1997, Kubic et al. separated the binding and inhibiting RNA aptamer against the interferon gamma (INF-γ) which caused the inhibition of MHCI and ICAMI expression induction by INF-γ [29].

Selection of anti-viral aptamers

Some of these aptamers resulted in the elimination of virus cell cycle by interaction with the proteins necessary for virus proliferation and some of them were able to block surface binding proteins and consequently resulted in the prevention of attachment and entry of viruses into cells [30].

- In 1995, Pan et al. separated the detecting and neutralizing RNA aptamer against Rose Sarcoma virus to inhibit the binding of the virus [31].

Selection of specific aptamers for binding and inhibiting the function of enzymes

- In 1998, Brindonau et al. succeeded in isolating 2'-amino RNA aptamer by SELEX (as a new drug) for inhibition of phospholipase A2 enzymatic activity in patients [32].

- In 2011, Tzu-Wang Chang et al. succeeded in isolating the RNA aptamer specified for inhibition of enzymatic activity of botulinum neurotoxin type A [33].

Selection of aptamers for detection of small molecules

- In 1998 and some years later, one DNA aptamer for Sulforhodamine B, two RNA aptamers for sulforhodamine B and fluorescein and one RNA aptamer for malachite green were separated by Wilson and Szostak [34].

Aptamers for cell diagnosis

- In 1999, Bruno et al. detected Bacillus anthracis spore by a single stranded DNA (ssDNA) aptamer using magnetic beads [35].

- In 2005, Qin Pan et al. isolated the RNA aptamer detecting the strains of Solmonella enterica serovar Typhi containing type IVb pili [36].

- In 2007, Fan Chen et al. isolated the ssDNA aptamer detecting a virulent strain of Mycobacterium tuberclosis called H37Rv [37].

- In 2006, Vivekananda et al. isolated 25 sequences of the ssDNA aptamer identifying surface bacterial antigens of Francisella tularensis japonica [38].

- In 2007, Ikanovic et al. designed an optical biosensor based on aptamer for detection of Bacillus thuringiensis bacteria [39].

Aptamers as tools for drug delivery

- In 2006, Farrokhzad et al. prepared nano-capsules of poly lactic acid (PLA) containing drug and linked to them the special aptamer related to prostate cancer cells through the poly-ethylene glycol linkage (PEG) [40].

Using aptamers for designing biosensors (apta-sensors) and nano-biosensors (nano-aptasensors)

- In 2011, Lakshmi et al. designed a chemical-resistant nano-aptasensor, for detection of anthrax PA toxin based on single wall carbon nanotubes (SWNT) [41].

- In 2012, Jeffery Degrasse et al. isolated a selective DNA aptamer for detection of Staphylococcus aureus enterotoxin B (SEB) for designing nano-aptasensor on the basis of surface plasmon resonance (SPR) (Figure 2 – as seen in the figure, biotinylated apatamers have been stabilized on streptavidin-coated gold nanoparticles, and the above nanoparticles are also fixed onto gold discs and by use of corresponding device, signals from surface plasmon resonance (SPR) changes are measured after detecting the target ligand by aptamer.) [42].

APTAMER AS A PROPER TOOL IN MODERN METHODS OF DIAGNOSIS

Nowadays traditional methods based on immune-affinity assays, in which antibody molecules are used, while transposing with new methods based on aptamers-affinity assays [43].

Functions and features of modern determination methods based on immune-affinity assays:

1. Aptamers are produced in vitro conditions and they do not require any living organisms, to which they allow us to use any molecules regardless of it being toxic for the organism and separate exclusive aptamers for determination.

2. After separation and selection of exclusive aptamers by SELEX, we could easily reproduce and mass-produce it in high purity of specified aptamers.

3. Mass production expenses are very low and they have proved to be cost effective.

4. Nucleic acids (including DNA-aptamers) by having some functional groups can more easily be adapted to their target exclusive ligand. Without any malfunctions or lessening in tendency for binding with exclusive ligand in the specified domain.

5. Aptamers are originally stable in a broader domain of conditions.

6. Aptamers have very high tendency to synthesize and dedicate compared to antibodies.

7. Aptamers with high affinity can be used for determination and detection of different sorts of ligands such as toxins, allergens, sugars (that are weak immunogens), haptens, nucleic acids, proteins and different kinds of little biological and non-biological molecules like morphine and etc. can be separated and used. It is while in previous methods there were many limitations regarding to this matter [44].

USING APTAMERS MOLECULES IN DETECTION AND NEUTRALIZATION (INHIBITION) OF BOTULINUM NEUROTOXINS

As latterly mentioned, until today there have been many researches around the globe on these oligonucleotides with detection and neutralization purposes specifically on botulinum neurotoxins (such as type A).

Reports have indicated that aptamers molecules separated from library are suitable and proper for this matter [45].

Diagnostic purposes

In diagnosis of botulism agent as the one of biologic threat factors, we can separate some aptamers with high binding tendency with SELEX method. Aptamers separated to interact with botulinum toxin and also with different neurotoxin regions including catalytic domain can be very effective in diagnosis purposes. But catalytic domains are more efficient and useful in diagnosis purposes for neurotoxin types specially type E [46].

Inhibitory goals

In inhibiting and neutralizing this extremely lethal factor we can get our hands on molecules with inhibiting and neutralizing effects on operational sites, by investigating inhibiting effects of separated aptamers for exclusive connections with high tendency to catalytic site [47].

These aptamers might hinder the activation of this operational site by connecting to de-activated catalytic site of the toxin’s body or by binding themselves to the freed catalytic site and cause the enzyme activity to stop [48]. In fact, inhibiting this position’s enzymatic function leads to restraining the toxin’s function. But antidotal aptamers can do the neutralizing process by connecting to other sites like connector sites and actually prevent the toxin from connecting to the cell and entering it [49].

Separating the aptamer against the catalytic domain of botulinum neurotoxin for recognizing and counteracting this toxin

Choosing the catalytic site from other operational sites of botulinum neurotoxin is important according to reasons mentioned below:

1. Results gained from conducted studies around the world show that this operational site is very suitable for getting the recognizing and counteracting goals.

- In 2011, Tzuu-Wang Chang et al. separated RNA-aptamer exclusively for inhibiting botulinum neurotoxin type A enzymatic activity [50].

- In 2009, Fang Wei et al. used separated aptamer for recognizing botulinum neurotoxin type A in designing electrochemical sensors [51].

- In 2009, Xinhul Lou et al. separated the special conjugative aptamers to catalytic domain of recombinant botulinum neurotoxin type A for recognizing this neurotoxin [52].

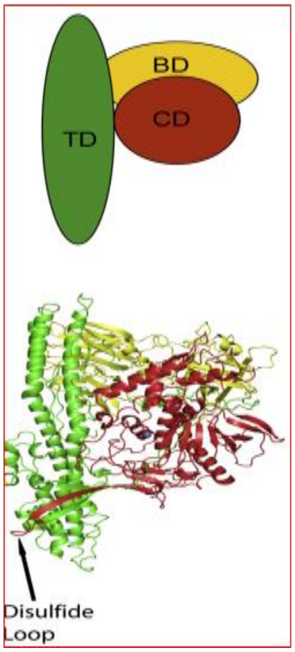
2. The main and operational part of this neurotoxin is the catalytic part and the quality of this neurotoxin is basically related to this part, in a way that said toxin will have no effect or special toxic function without this part [53]. So in conclusion the diagnosis and neutralizing value of this location will be much higher than other ones. And recognizing this location will lead to the certain recognition of infection to this type of neurotoxin, whereas recognizing other locations won’t necessarily mean that and it’s possible that other locations be used as recombinant with other factors [54].

3. The unique structure of botulinum neurotoxin type E and the importance of epitopes situated on this location and symmetric bond to the connector site, in a more general sense epitope makes the selection of this site for the toxin for this serotype exclusively more suitable (Figure 3 – the red represents the catalytic region, the green color indicates the translocating region and the yellow color indicates the binding region of the neurotoxin. As can be seen, both the catalytic and binding regions are located on one side of the translocating region, not on two sides as seen in the other types.) [55].

RESULTS AND DISCUSSION

Studies have shown that aptamers with central core of 75-100 base length are not suitable aptamers and on the other hand aptamers with the central core of lesser than 15-20 base also cannot be suitable aptamers [56]. If the length of aptamers fragments is longer than the above:

Figure 3. A schematic representation of second structures of neurotoxin botulinum type E and a symmetric relationship between catalytic and binding domains of toxin.



1. The possibility of creating similar sequences with primer in the central core is increased and with binding primer to this central parts and amplification, no particular fragments with shorter length will be the outcome.

2. On the other hand the possibility of connecting flanking sites of 2 sides (primer binding sites) with central sequences of various fragments, is increased and will cause an unhindered length increase and generation of fragments with larger sizes and PCR product of these two processes will be seen as smear.

3. Also the larger of these fragments be their particular operationally will also be decreased. Because after the formation of the 3rd structure there will be more binding sites to bind to target protein that each of which will have different affinity and can bind to our protein from different sites and positions and one of these position might have a high infinity to our target protein but no other position. So in conclusion the average affinity will drop and this means the decrement of specificity (affinity and specificity are two completely separate parameters) [57-59].

If the length of aptamers fragments is shorter than the above:

1. We'll witness a significant decrease in genetically variety of aptamer fragments and this will significantly limit our screening stages.

2. On the other hand the 3rd structures and conformation of aptamer which is the basis of aptamers binding to biomolecules will not form properly or won't form at all and this means the inefficiency of aptamer.

3. Another problem is the drawback in performing PCR and evaluating the target binding which distinguishing it from dimer primer is not easily achievable.

4. On the other side we'll face up to a huge problem in the purification of a production with such dimensions. Studies have shown that lengths about 40 base will be adequate and as we advance to larger or smaller numbers we will encounter the problems mentioned above more frequently although we are free to choose between 15-75 (20-100 according to some sources) (Figure 4) [60-62].

Figure 4. A schematic form of the single-stranded oligonucleotide structure of aptamer with a central core of 40 nucleotides. Scientifically and statistically, there is the probability of having a variety of 440 aptamer fragments (which is 1024 fragments) with a central core of 40 nucleotides, but optimistically virtually this variation is about 1015 aptamer fragments.

$4^{40} = 10^{24}$ (fragments)
Flanking site 2 (~ 20 bp)
(3′ R′ Primer binding site)

In Figure 5 the schematic form of SELEX cycle on RNA aptamer library is shown. The primary library made of DNA is firstly turned into a RNA library during a transcription process and after being added to nano particles covered with target proteins and performing the stages of washing and reunifying by performing the process of "asymmetric RT-PCR", is transformed to c-DNA and after single threading and removing the non-original strand the next cycle is again continued by transacting on the product mentioned above and creation of a RNA aptamer library [63-65]. It is necessary to perform a stage of negative selection in the presence of similar proteins.

Figure 6 shows the increment of aptamers' affinity as with the progress of SELEX stages, which is evaluable using the

ELASA method (aptamer-based ELISA). Then we can perform a software based test on aptameric sequences using M-fold software.

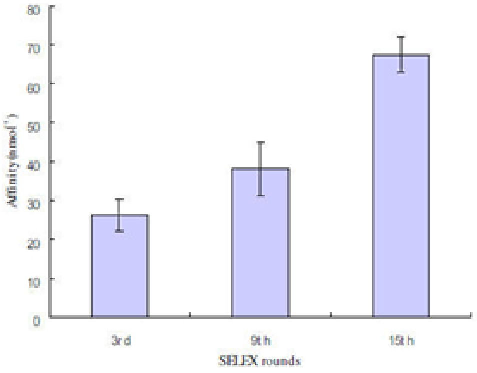
This investigation will give us the chance to understand how nucleotide changes in the final aptameric sequences causes a change in operational structure [66]. On the other hand, the software itself will predict different kinds of possible operational structures for that aptamer molecule and it will also suggest the best possible form. Sometimes the result of such investigations will show us the existence of a necessary operational site in the central core, which will have a key role in binding to the target protein [67].

Figure 6. Binding affinity of aptamers increases with the progress of the SELEX steps



In a more accurate investigation for getting aptamers with higher affinities and higher specificity for binding to target protein we can put this specified operational site in the central core of a new aptamer library and perform the SELEX stages on that library again (Figure 7a and 7b) [68].

In Figure 8 the pattern of aptamer nucleotides labeled with digoxigenin (DIG) recognizing the target molecule is shown, so in part A the flow cytometry is used for identifying the interaction between aptamer and target molecule and in part B the chemiluminescence is used. Part C shows the chemical formula of digoxigenin [69].

CONCLUSION

The most recent discoveries related to aptamer molecule shows the existence of particular properties and unique attributes in this biomolecule for the means of getting to the considered goal and the beneficial role of this molecule as a powerful tool for recognizing and neutralizing (inhibiting) the threatening factors shows great promise. These days the traditional methods for recognizing the biological factors based on immuno-affinity assays in which antibody molecules are used are being replaced with the new methods based on aptamer-affinity assays. The selected aptamers during the different stages of SELEX, with the ability of creating exclusive bonds and high tendency to interact with operational sites of biologic factors, in addition to having precise and fast recognition of this factors e.g. utilizing them in biological nano-sensors based on aptamer (nano-aptasensor), they could also be used in neutralizing and inhibiting the function of these threatening biological agents.

VARIA

Are there only records of success in urology, or are there errors, mistakes, and risks as well?

Viorel Tode

The history of urology dates back to the antiquity, before Christ. The panels decorated in low relief of Saqqara, located at the Institute for the History of Medicine in London, depict the oldest surgical procedure in the world – the circumcision – dating from 2200 BC.

Hippocrates knew about genito-urinary disorders and treated them with medication, leaving bladder stones to be treated by lithotomists.

Cystolithectomy is also known to be dating back to ancient times, having been performed in Egypt, the Middle East, and Ancient Greece.

Urology has always been and still is, an exceptional profession, requiring both intelligence and effort in scheduling and executing the necessary techniques, in assuming risks, and in accomplishing spectacular results.

I will only mention here several of the events that marked the exceptional evolution of urology: defeating pain using anesthesia, progresses of pathological anatomy, the development of the cystoscope by Nitze and the beginnings of endoscopic explorations, the use of Roentgen rays in medicine, Pasteur's contribution to the study of microbes and Lister's in asepsis and antisepsis, the renal transplantation – using which, the urologist gives another lease of life to the patient – the tremendous achievement of Mathias, Jaboulay and Alexis Carrel, percutaneous, laparoscopic and robotic urology as well as other exceptional accomplishments.

The title of this article is addressed as a question: are there only records of success in urology, or are there errors mistakes, and risks to take as well?

However, the word urology can be replaced by any other specialty: surgery, gynecology, ENT, ophthalmology, and why not even internal medicine, neurology, psychiatry, endocrinology, family medicine, and so on.

Hippocrates said: "In medicine, the one who has to be praised is the one who makes the fewer mistakes".

Reflecting upon my professional life, recalling now at senescence, I concluded that I remember less about my many successes in healing patients, but have more vivid memories of some intra or postoperative complications that I have lived intensely.

One can hardly forget, for instance, bleedings that were hard to contain, the slip of a ligature on a vascular pedicle, a vena cava or iliac tear, a large posttraumatic retroperitoneal hematoma, a complex kidney rupture, a pelvic fracture that affects the urethra, urinary bladder or rectum, a postoperative urinary fistula and so on.

In 1971, in medical literature, the second edition of a valuable work by Academy Professor Th. Burghele was published in French – "Erreurs, fautes et risqué en Urologie", from which I will cite only the title of the first chapter – The complexity of urology, factors of error and faults (La complexite de l'urologie, factor d'erreurs et de fautes) and the title of the last chapter – The ontological aspects of faults and errors in urological practice (Les aspects deontologiques des fautes et des erreurs de la practique urologique).

Specialty medical journals are rich in articles presenting, and rightfully so, the successes accomplished by urologists, however, very few publish the occasional failures: errors, mistakes, and risks met or faced during surgery. Professor Th. Burghele once introduced a chapter in the journal "Surgery" – deaths on the surgical table – but after a few case studies, no one published anything related anymore.

It would be difficult for me to believe that in medical practice, one could fully believe one never made a mistake. Medical mistakes in general, and surgical-urological ones in particular, given the human element on which the work is being done, can sometimes generate severe consequences and are thus not admitted.

Momentous errors punishable by law notwithstanding, some mistakes often look insignificant, that occasionally pass undetected by some and that only a urologist in the know would notice. Those are the kinds of mistakes that sometimes would genuinely shake the morality of the urologist tougher than any legal sanction.

Technical progress, modern means of investigation, and new therapeutic options have made urology more benign, with lesser risks and fewer possibilities for errors. The extension of urology to new areas, some not attempted before, exposed other possibilities for complications and postoperative incidents. However, with all the developments of urology and medicine in general, what we still only partially fathom are the reactions of the organism.

Despite technical or analytical errors, it is sometimes possible for the organism, utilizing its reactions to avert or at least limit important consequences that might follow. Other times, through a lack of response, paradoxical or unanticipated reactions, complications and mistakes might be aggravated, thus requiring re-intervention to ensure positive results.

No one in the world, in any profession, can be above mistake: the urologist has the moral duty to do whatever he can to minimize errors.

All active people, and especially those who try new things in the name of growth made mistakes. Progress in all fields, in medicine and particularly in surgery, meant repeated attempts with a mistake, repetition, effort, and sacrifice, and people often paid dearly for surgical advance. But often, from mistake came more knowledge than from success.

To admit errors and to look for their source is the essential condition for a better tomorrow.

Marshal Foch, the highest commander of allied armed forces, victorious in World War I said: “of course I have made many mistakes, but if I hadn’t made them, I wouldn’t have accomplished everything I did in 1918”.

But to misstep as little as possible is no simple or easy task. For the urologist, few mistakes mean having thorough professional training that never ceases to perfect.

For the urologist, making few mistakes means having the chance to stay young at heart, to have the will to constantly improve, and at the same time to keep an unshaken belief in the promise of a better future. It also means understanding and cherishing this ingrate but unimaginably beautiful profession which is urology. And to assimilate it well, the urologist is bound to forfeit his youth, sacrifice his freedom, and surrender all thoughts.

In my personal opinion, a resident in urology should only train in clinics that alongside highly qualified faculty, have the means of instructing residents in all areas of the specialty: open surgery, low and high endoscopic urology, ESWL, abundant imaging possibilities, laparoscopy, robotic surgery and so on.

Once a specialist, the urologist has to constantly oversee his professional progress and keep up with all modern attainments in our specialty.

To obtain the title of the primary physician, there should be a return to a competitive exam form factor, with a limited number of positions, exams not attestations, held before a commission with valued members of the faculty from the country. The primary physician title is a higher degree within the specialty, one that should be aspired to, and only received by the valuable urologists.

Competitive exams should be set to obtain the position of head of the unit, on a period of no more than 4 or 5 years, same as the presidency of the country. The head of the unit should be the best trained professional, highly competent, and capable of solving the most complex cases, known through his profession and case studies held at conferences, symposiums, or published in specialty publications.

There was once even an institute for specializing and perfecting doctors in Romania, housed within Fundeni Hospital. Bygone…

The urologist, like any other person, can slip, and without a doubt will make errors the more he works and the more intricate, tough problems he attempts. But what portrays a proper urologist is not that he is never mistaken, but the fact that he recognizes the mistake and has the conscience and power to fix it.

Celsius, the great anatomist and surgeon of the middle ages said from the beginnings of surgery:” recognizing mistakes is only fit for the intelligent man”.

Diagnosing and identifying complications that necessitate re-intervention is far from being a simple, easy feat.

The numerous paraclinical investigations available have particular importance in appreciating postoperative evolution and occurrences, with imaging being one of the most important means of investigating in diagnosing and indicating re-intervention.

However, all those, without minimizing their importance, cannot replace the clinical assessment, repeated examinations, careful and continuous observation of the patient, and especially the evaluation of the sometimes subtle signs of aggravation.

The character Sherlock Holmes, by Sir Arthur Conan Doyle, said: ”You know my method. It is founded upon the observation of trifles”.

Joseph Okinczy wrote the famous book that will forever remain in the history of surgery ”The small rules of perfect surgery”.

Due to the rapid progress of the last years in the area of biomedical sciences, and in cellular and molecular biology, genetics, and medical imaging, in particular, some clinicians developed the tendency to put less of an emphasis on the anamnesis and clinical examination, relying solely on "adequate" paraclinical examinations, which often prove to be inadequate. This leads frequently to not only unnecessary spending but to diagnosing faults which reflect on the patient's well-being.

The problem of re-intervening reflects upon the character of the urologist and his professional condition in the most profound dimensions of the specialty and subtlest forms of knowledge.

Whenever complications occur, the experience, expertise, and professional value, as well as the temper of the urologist are often put to the test.

Urology was not always as we see it currently. To achieve perfection and the shine we see today, every civilization contributed in spirit, every century laid its rocks, every people brought their input. In its constant evolution, it was only natural that the passive attitude towards incidents and complications had to change.

Currently, such accidents can undergo surgery, a large number of patients can be healed. A detailed study has shown how to best avoid those incidents.

Sure enough, several re-interventions have nothing to do with the primary procedure, nor any urological error. But when in doubt and more importantly when errors exist and the following complications require surgical remedy, re-intervention, no matter how severe, is the only act which allows the urologist to fix, often successfully, that which was wrong.

Within our need and tendency to better ourselves, we must not only see the mistakes of others. It would be despicable to comment in bad faith any errors of our colleagues while justifying our own.

The constant growth of urology offers indisputable potential for great success, but also occasions to fail.

As far as I am concerned, whenever I made a mistake, I prayed to the providence that it be the last one.

But I never forgot that the urologist, as long as he is working, cannot say that he has made his final mistake.

REVIEW

A review of biovitroceramic PAW1 – Romanian bioactive implant material for ossiculoplasty

Marian Radulescu[1], Adela I. Mocanu[2]

Abstract: *A successful ossiculoplasty (reconstruction of the ossicular chain of the middle ear), even now, almost a hundred years after the first attempts and countless tested materials, remains a challenge through the complexity of the surgical act and through the repeated attempts to find the most adequate prosthesis to re-establish, in the long term, the sound conductive mechanism.*

In this article, we present a review of the main implanted materials, including the biotechnological aspects of ossicular chain reconstruction with an emphasis on the Romanian contribution to this field of study.

Keywords: *prostheses, implants, ossiculoplasty, ceramics, ossicular chain, biotechnology, biocompatibility, biovitroceramic PAW1*

INTRODUCTION

Ossiculoplasty is a surgical procedure used to restore hearing loss by reconstructing the ossicular chain mechanism between the tympanic membrane and the oval window, in the presence of a discontinuity or fixation, with or without a concomitant disease. The medium-term and especially the long-term success of this intervention depends on several important factors: the skill of the surgeon, the material used in the reconstruction of the ossicular chain, and, most importantly, a preserved, quality middle ear.

Chronic suppurative otitis media (COM), with or without cholesteatoma [1], is the most common pathology that influences the outcome of surgery and the long-term functional and anatomic results. The functional results become even more important if you consider that hearing loss of variable etiology represents one of the most challenging public health issues confronting the world's population [2]. "The integrity of the auditory system is one of the prerequisites for the acquisition and the proper development of oral language and a person suffering from hypoacusis is more likely to have poorer professional results than his colleagues, and will be less competitive in the labor market, and will have smaller chances to complete higher education" [3,4].

The next most important factor influencing results is the type and the quality of the material. Over time many types of materials have been tested (biological and synthetic), some entering into medical practice a shorter period, others remaining in current use, but the surgeon's choice for the ossicular chain reconstructions depends on their own experience in the field, the ossicular deficiency or the patient's immunological status [5]. The purpose of all these attempts is to implant a type of material with excellent biocompatibility, and stability, to provide natural sound transmission with the minimum risk of potential bacterial colonization or graft rejection [6].

THEORY AND CONCEPT

Ossicular substitution or reconstruction has been attempted with an array of materials but the only conclusion that has been drawn is that "the ideal prosthesis for ossicular reconstruction should be made of a material that maintains

adela.ioana.mocanu@gmail.com

its shape, rigidity, and acoustic properties, as well as being cost-effective. This material should also be biocompatible, safe, and easily inserted and modified" [7].

From the acoustical point of view, a prosthesis is well designed, if its shape and material reach a high stiffness combined with a low mass but is also small, relatively cheap, and easy to modify [8,9,10,11].

From this point of view, titanium has advantages compared with gold, ceramics, or plastics because of its low density and high mechanical strength. These properties of titanium significantly reduce possible loss in sound transfer due to internal resonances. The higher mass of gold and ceramic prostheses decreases the motion of the entire system above the first resonance.

This inertia influence can also be seen by a decrease in the first resonance frequency of the (reconstructed) middle ear system. "By contrast, the low mass of the light titanium prostheses contributes to a better sound transfer performance, especially in the high-frequency range." [12]

A further significant parameter is the quality of prosthesis coupling to both tympanic membrane/malleus and stapes. The dynamics of the reconstructed middle ear are very sensitive to where and how the prosthesis is coupled to the tympanic membrane and ossicles, to the spatial direction in which the prosthesis is oriented, and to the prosthesis attachment (near rigid or rather loose attachment). In a patient, the prosthesis attachment may be influenced by the resulting tension that is achieved both by the surgeon and by postoperative wound healing.

Prosthesis placement is paramount for obtaining good functional results, but this represents no guarantee that postoperative migration relative to the malleus handle, TM, or stapes will not occur [13,14]. This is highly dependent on the skill of the surgeon; the type of prosthesis and we should never forget that medical research can sometimes require a high degree of abstraction and theorization [15].

"Ossicular reconstruction materials are categorized as autografts, homografts, and alloplastic prosthetics. Each of these materials has advantages and disadvantages for use in the middle ear" [7].

BIOLOGICAL MATERIALS

Hall and Rytzner (1957) performed the first chain reconstruction using autogenous incus [16]. Several otologists, including Farrion, Sheehy, and Guilford, began reporting on the success of using autografts for ossicular reconstruction, especially for the body of the incus [17]. However, the patient's incus is not always available for repositioning and Farrion first advocated the use of cortical bone as an ossicular substitute [17,18].

As a biological alternative to ossicles, cartilage has been extensively used in tympanoplasty and ossiculoplasty [18]. Autologous tragal and/or conchal cartilage is, however, not always suitable for ossicular chain reconstruction, especially in cases where the stapes arch is missing since they do not have the required mass, stiffness, and thickness [19]. Zini et al. (1984) introduced ossicular prostheses made from costal cartilage and reported no extrusion at 10 years of follow-up with stable functional results over the years [19].

Autologous materials presented a high degree of tolerance within the middle ear and provided reliable hearing results. Their disadvantages were the laborious and time-consuming sculpting into the required shape and the scarceness of material in chronically diseased ears [4] loss of rigidity (especially with cartilage), and possible fixation to the soft tissues of the middle ear [17].

Homografts (as an option for unreliable autografts) were first used for middle ear reconstruction in 1966 by House and colleagues and later led to the use of "irradiated ossicles, cartilage, and even homograft tympanic membranes with en bloc ossicles" [20,21]. The hearing results and biocompatibility of homografts and autografts proved similar but the risk of disease transmission of HIV and prions (i.e., Creutzfeldt-Jakob disease) brought their decline in use – see Table 1.

Donor (D) – Receiver (R) Relationship:
1. Autologous: D ≡ R
2. Isologous: D·R Homozygotic Twins
3. Homologous (Alloplastic): D·R Same species
4. Heterologous (Xenoplastic): D·R Different species

Donor Situs (D.S.) to Receiving (R.S.) situs Relationship:
1. Orthotopic (same situs): D.S. ≡ R.S.
2. Heterotopic (different situs): D.S. ≠ R.S.

Although many surgeons preferred biological prostheses due to increased compatibility with the middle ear and low rate of rejection, the lack of materials and prolonged intraoperative time led the researchers to look for the ideal material in the reconstruction of sound conducting mechanisms.

SYNTHETIC MATERIALS

Other than the natural or biological materials (autologous and homologous), polymers, ceramics, and metals are currently used for ossicular chain reconstruction, each with its advantages and disadvantages. These synthetic materials are defined as biomaterials.

In 1958, Shea used for the first-time polyethylene prostheses (Polytef – Teflon and silicone elastomer – Silastic) for middle ear reconstruction [17] with excellent short-term hearing results. The high extrusion rate, significant middle ear reactivity towards synthetic materials, and risk of penetration into the inner ear [17] caused this material to gradually drop out of use.

Table 1: Types of natural biomaterials used in ossiculoplasty

Natural Biomaterials (Grafts, Transplants)				
Type	**Status**	**Donor–Receiver Relationship**	**Species**	**Author, Year**
Autologous	Fresh	Orthotopic	Remodeled malleus	Wullstein, 1953
		Heterotopic	Cartilage	Williams, 1958
			Tragal cartilage	Utech, 1960
			Septal cartilage	Jansen, 1962
			Rib cartilage	
			Mastoid cortical bone	
Homologous (Allo)	Preserved	Orthotopic	Isolated ossicles	Portmann, 1959
			Ossicular chain	Marquet, 1966
		Heterotopic	Mastoid cortical bone	Wullstein, 1952
			Septal cartilage	Jansen, 1960
			Rib cartilage	
			Meniscus cartilage	
			Dentine	Zini, 1967
Heterologous (Xeno)	Preserved	Orthotopic	Veal incus	Sultan, 1983
		Heterotopic	Veal rib cartilage	Zini, 1959
	Normal	Normal	Coral	Robier, 1987
				Schmorll, 1990

After almost 20 years of research, in 1976, Shea reported on the use of a high-density polyethylene sponge (Plastipore), a porous, nonreactive material that could allow the in-growth of tissue [22]. "A similar thermal-fused porous polyethylene (Polycell) was developed later and allowed the prosthesis to be coupled to other materials, such as stainless steel thus enabling various prosthesis designs" [17]. The most-reported problem of such porous materials was the high extrusion rate when in direct contact with the TM. However, a disc of cartilage placed between the head of the prosthesis and the tympanic membrane gives excellent long-term results even today [22,23].

In 1979 the era of ceramics in ossicular reconstruction begins by introducing a few categories of alloplastic materials, either bioinert or bioactive. Implantable materials that do not release detectable trace substances are termed bioinert. The prototype bioinert material is dense aluminum oxide ceramic (Al_2O_3), popular in Germany and Japan in the 1970s. The implant can be fitted to the under-surface of the tympanic membrane without cartilage coverage [24].

By studying the way, the body reacts to the implanted materials, there can be three major recipients defined (Tables 2, 3, 4):

● "bioinert" – the body does not react to the implant material.

● "bio-tolerated" – the local tissue regards the implant as a foreign body but does not react, the material is not excluded.

● "bioactive" – the local tissue reacts and tends to create a stable bound to integrate it [6].

"Bioactive implants, such as glass-ceramic (Ceravital), were biocompatible and reacted with surrounding soft tissue and adjacent bone allowing a coupling between the implant and the ossicle" [19,25] and were used, with various results, around the world, even in the former communist bloc, including Romania [26].

Hydroxyapatite, found in the mineral matrix of living bone, was introduced for tympanoplasty surgery in 1984 by Grote (calcium phosphate ceramic) [27]. It is a bioactive material that can be easily integrated into surrounding tissues (bone). The first results by Wehrs et al. reported functional success and a low extrusion rate 4 years after implanting hydroxyapatite incus or incus/stapes prosthesis. Since that time, this material has been adapted to various uses and prosthesis designs [17,20].

Titanium prostheses were developed and first used in Germany in 1993 and have been growing in popularity ever since. The material is rigid and biocompatible just like hydroxyapatite, but much lighter. It is also nonmagnetic and allows it to be manufactured in many precise shapes. “Most of the titanium prostheses possess an open head, allowing better visualization during placement” [17].

Table 2: Types of synthetic bioinert materials used in ossiculoplasty.

Name	Composition, Chemical structure, Family, Order	Author, Year
ALUMINA FRIALIT CORINDON	Al_2O_3 Oxide Ceramics	Plester & Jahnke, 1979
BIOCERAM	Al_2O_3 Y_2O_3	Yammamoto & Ywanaga, 1983
MACOR CERAMIC	Fluor phlogopite mica-Borosilicate glass $SiO_2 \cdot MgO \cdot Al_2O_3 \cdot K_2O \cdot B_2O_3 \cdot F$	Pauler & Jahnke, 1984
VITROCARBON	Glass - Carbone	Blemke et al. 1987

Table 3: Types of synthetic bioactive materials used in ossiculoplasty.

Name	Composition, Chemical structure, Family, Order	Author, Year
BIOGLASS 45-S-5	Silicon-Phosphorus Bio-glass $SiO_2 \cdot CaO \cdot Na_2O \cdot P_2O_5$	Hench et al., 1970
CERAVITAL	Silicon-Phosphorus Bio-vitro-ceramic (Hydroxyapatite – Glass) $Li_2O \cdot ZnO \cdot SiO_2$	Brömer et al., 1973
CERABONE A-W	Hydroxyapatite – Glass- β-Wollastonite ($CaO \cdot SiO_2$)	Kokubo et al., 1982
IMPLANT L-I	Hydroxyapatite – Glass- β-Wollastonite ($CaO \cdot SiO_2$)	
BIOVERIT I	Mica – Apatite – Glass $SiO_2 \cdot (Al_2O_3) \cdot MgO \cdot Na_2O \cdot K_2O \cdot F \cdot KO \cdot P_2O_5$	Holland &Vogel, 1987
BIOVERIT II	Mica – Glass – Corderite	Holland & Vogel, 1993
BIOVITROCERAMICS PAW-1	Fluro-hydroxyapatite – Wollastonite – Glass $B_2O_3Fl_2$	Rădulescu & Negreanu, 1993

Table 4: Types of synthetic bio-tolerated materials used in ossiculoplasty.

Name	Composition, Chemical structure, Family, Order	Author, Year
PALAVIT	Vinyl-acrylic resin	Wullstein, 1952
SUPRAMID	Polyamide (Nylon)	Kley, 1955
POLYETHYLENE	Non-porous, low-density polyethylene	House, 1960
TEFLON	Polytetrafluoroethylene (C2F4)n (PTFE)	Shea, 1962
NON-OXIDATIVE STEEL TANTALUM SILVER ZIRCONIUM TITANIUM	Non-oxidative metals	Schucknecht, 1971
PROPLAST	Polytetrafluoroethylene (TEFLON) – Carbon fibre composite	Shea, 1974
PLASTIPORE	High-density polyethylene sponge (HDSP)	Shea, 1974
POLYCEL	Thermal fused HDSP	Fisch, 1981

Classification of Synthetic Biomaterials:

1. Destination:
   - 1.1. Tissue
   - 1.2. Organ
   - 1.3. Function

2. Composition:
   - 2.1. Monocomponent
   - 2.2. Policomponent

3. Structure – Mass - Form:
   - 3.1. Monostructure
   - 3.2. Polistructure

4. Relationship to Host (Recipient):
   - 4.1. Biotolerated
   - 4.2. Bioinert
   - 4.3. Bioreactive (Active, Bio-reactive, Bioactive)
   - 4.4. Composite (e.g., Tolerate + Active)

BIOVITROCERAMIC PAW-1 AND THE ROMANIAN CONTRIBUTION

Synthesized in 1990 by Dr. Ing. Popescu-Negreanu, PAW-1 was tested physically, chemically, and biologically (in vitro and in vivo) between 1991 and 1992 and homologated on March 31st, 1993.

Bio-vitro-ceramic PAW 1 is a solid, bio-reactive material, made up of fluoro-hydroxyapatite and wollastonite microcrystals encompassed into a vitreous mass (glass). Hydroxyapatite, which is the mineral matrix of living bone, is a well-tolerated osteoinductive material that does not produce necrotic phenomena in adjacent tissues and does not give foreign body reactions [26] – see Table 5.

Table 5: Taxonomy of PAW1.

General Taxonomy of PAW1
Class: Solids with biphasic structure (crystalline and non-crystalline)
Order: Ceramics
Family: Bio-vitro-ceramics
Genus: Silicon – Phosphorus
Species: Controlled porosity
Variety: α - closed porosity (dense) β– opened porosity (porous)
Special Taxonomy of PAW1
Synthetic
Destination: Organ
Composition: Poli-component
Structure – Mass – Form: Monostructure
Relationship to Host (Recipient): Bioactive

Medical use:

1. Dentistry: Central Military Hospital, Bucharest since June 1993
- Parodontopathy
- Granules

2. Oral and maxillofacial surgery/Esthetics: Prof. Burlibașa, Prof. Gănuță since 1993
- Granules
- Shaped implants

3. Orthopedics: Central Military Hospital, Bucharest and Foișor Orthopedics Hospital, Bucharest, Prof. Popescu Mihai since 1993
- Granules
- Shaped implants

4. Neurosurgery: “Bagdasar-Arseni” Neurosurgical Hospital, Bucharest, Prof. Dănăilă since 1994
- Shaped implants

5. Otorhinolaryngology (Otology): IFACF-ORL Prof. Dorin Hociota, Dr. Marian Rădulescu since June 1993
- Ossicular chain implants (PORP, TORP)

Chemical composition:
1. Fluorohydroxyapatite: $[Ca_{10}(PO_4)_6(OH)xFl_2\text{-}x]$
2. β-Wollastonite ($CaO \cdot SiO_2$)
3. Boron trioxide: B_2O_3
4. Fluoride: Fl_2

The material is obtained by thermally controlled crystallization (ceramization) of glass from the Silicium-Calcium-Magnesium-Phosphorus system ($SiO_2 \cdot CaO \cdot MgO \cdot P_2O_5$) with minute additions of Borum trioxide (B_2O_3) and molecular Fluoride.

Biological properties:

1. Biocompatibility:
- Predictive: Good, due to the identity of the crystalline phase of the material to the mineral phase of the mature bone.
- Experimental: tested through the low rejection rate of middle-ear implants.

2. Biodegradation:
- Predictive: Null without inflammation/infection. Osteogenesis on the implant-tissue interface.

Identical to the bone with inflammation/infection.
- Experimental: Clinical – the study of rejected implants degradation

Paraclinical – Rx for integrated implants/HP for rejected.

3. Bioactivity:
- Predictive: Good, based on the physical and chemical structure.

Porosity – cell colonization and mechanical anchorage.

Chemical structure: Chemical anchorage (direct) = covalent ties at the implant-tissue interface. Osteogenesis on the interface.
- Experimental: tested through the rate of histological integration and rate of tympanic membrane perforation.

4. Bio-functionality:
- Predictive: Good, based on mechanical and vibro-mechanical properties.
- Experimental: tested through therapeutic efficiency (audiological gain – dB): Air-bone Gap (ABG) pre-operatively vs. post-operatively.

CONCLUSION

Although numerous techniques and materials have been used for ossicular reconstruction, the quest for the ideal prosthesis and the best-suited materials is ongoing. This research took place all over the world during the past century and even developing countries such as Romania played a role.

The autochthonous bio-vitro-ceramic PAW1 proved to be a reliable, resilient material with a high degree of biocompatibility and good functional results.

The best combination of biocompatibility, toughness, ease of shaping, and inserting are still to be found.

Today, autogenous, and alloplastic prostheses are equally used with good outcomes, but the final decision remains to the surgeon, and it would be wise that he chooses the one that is most comfortable for him and provides consistent and favorable results.

A review of the need to provide hyperbaric medical research infrastructure for the treatment of combat-related injuries

Fardin Dolatimehr[1,3], Shahram Oliaei[2,3], Esmaeil Mehraeen[4]

Abstract: *HBOT has been used quite extensively in the last couple of decades. But there are not many centers that offer this treatment, even in civilian situations. This review has described the rationale and clinical evidence for equipping medical centers with HBO systems, especially in military areas.*

A narrative review of all the literature available on HBOT in combat-related injuries, studies were retrieved from systematic searches on Science Direct, PubMed, SCOPUS, ISC, Google Scholar, and by cross-referencing until 2020.

First, the etiological mechanisms of action of HBOT were discussed. Furthermore, we have provided an overview of 117 studies that clinically investigated the effect of HBOT in the last couple of decades. Therefore, based on the number of studies showing a positive effect, to speed up the treatment process, especially in war-related injuries, it is better to provide its infrastructure and equip hospitals and centers with HBO.

Keywords: *hyperbaric, hyperbaric therapy, trauma, war trauma*

INTRODUCTION

The trauma of firearms has caused many casualties in human societies since world wars military facility up to date with the advancement of military facilities, and a large part of the medical staff has always been dedicated to treating and improving the disability of injuries caused by war trauma [1]. Many studies have been done in this regard, and the beneficial effect of hyperbaric treatment has been proven [2].

Hyperbaric Oxygen therapy is the treatment of patients with oxygen respiration in a high-pressure treatment room. Increasing oxygen and delivering it to tissues has beneficial effects for various diseases. Some of these injuries are related to combat-related injuries [3]. Although the number of hyperbaric oxygen therapy sessions varies depending on the type of disease, and there is no absolute definition for the duration or pressure of oxygen in each treatment session, when hyperbaric oxygen therapy timely and properly is done, the evolution and the final result will be improved [4]. However, due to the technical limitations of treatment such as the need for a high-pressure treatment room, adequate oxygen, and compressed air supply, medical and paramedical staffs, the centers that provide this treatment are not numerous, even in civilian situations [5]. Hyperbaric Therapy Working Group investigates the possible military applications of hyperbaric oxygen therapy and defines the terms of its use. The amount of damage caused by war traumas inside or outside the city varies depending

on the geographical location, which necessitates a comprehensive study to provide a suitable solution to prevent trauma-related injuries [1]. Although it is not possible to set up hyperbaric treatment centers near the operation site, it seems possible to organize medical evacuation routes. It appears that this collection of information in the form of a review paper will benefit to help shorten the overall treatment time of combat-related injuries and optimize the final recovery by building the right infrastructure [6, 7]. It appears that this collection of information in the form of a review paper will benefit to help shorten the overall treatment time of combat-related injuries and optimize the final recovery by building the right

METHOD

To find available data and information in the literature on the role of Hyperbaric oxygen therapy (HBOT) induced combat-related injuries via vasoconstriction and Increase oxygen supply after trauma and we performed a search in multiples data banks such as Science Direct, PubMed, SCOPUS, ISC, Google Scholar, and the paper published Until 2020 were reviewed.

It should be mentioned that the search terms and keywords for evaluation of all published papers in this manner were "Hyperbaric Oxygen Therapy", "Refractory Osteomyelitis ", "Intracranial Abscess", "Radiation Injuries", "Burns", "Wound", "Traumatic Wound", "Traumatic Brain injury", "crush injury", "military Medicine" and "inflammation", "Acoustic trauma "Also, we used MESH term "OR" operator between synonyms keywords and "AND" operator between independent keywords for finding articles and papers as well as articles with the most consistency with our goal. For a review of all papers, we had inclusion criteria, and in 203 published papers which in them the hyperbaric oxygen therapy in combat-related injuries, 117 papers were selected for review and citation of all published papers.

DISCUSSIONS

The effects of hypoxia vary depending on the cause, whether the condition is acute or chronic, as well as the overall health of each individual. Cellular hypoxia may occur in multiple organ failure syndromes due to increased tissue oxygen demand or due to the ability of oxygen to break down at the cellular level; to repair, oxygen transfer and metabolic support are important components of treatment.

Definition and mechanism of action of HBOT

Since the 1960's HBO has been used for the treatment of various diseases and illnesses [8]. HBO involves the respiration of pure oxygen under high air pressure [8]. HBOT often use in complex trauma. Lamm [9] and Appaix [10] are credited for their pioneering work on the role of HBOT in these two conditions

According to the laws of physics and physiology, breathing oxygen at high pressure increases alveolar oxygen pressure and pharmacological effects with increased arterial O_2 content leading to improvement of ischemic state due to lack of oxygen such as chronic unhealed wounds, causes vasoconstriction and special antibacterial effect against anaerobic bacteria on the body [11].

In this procedure, the patient is completely enclosed in a special chamber, and by breathing 100% oxygen, the pressure inside the chamber gradually increases to more than one atmosphere [12]. So HBOT is a relatively time-consuming therapy for patients because patients must be physically present in the oxygen chamber [13]. HBOT is considered a safe therapy; however, side effects do occur in some studies. Contraindications to hyperbaric oxygen therapy are low, including untreated pneumothorax and some chemotherapy drugs such as bleomycin, which can lead to pulmonary fibrosis [14].

The effect of HBOT on the treatment of war traumas

Acoustic trauma

Acoustic trauma is damage to the auditory structures in the inner ear due to loud noise. Hearing loss and tinnitus are two of the most common disabilities caused by military veterans. Reports indicate a worrying increase in these complications in the military population [13]. Recent war scenes have seen soldiers face numerous dangers that lead to these effects, such as explosions, ototoxic chemicals, and loud noises [15]. Damage to the auditory mechanism can be caused by an explosion near the ear, shooting, or prolonged exposure to loud noises. Hearing loss, the fourth leading cause of medical visits to soldiers [16]. Of the more than 5,000 troops stationed in Iraq and Afghanistan who underwent audiometry, 1550 people have been reported to have been exposed to acute trauma of a sound explosion; of these, 72% have lost their hearing. Of all deployed personnel who underwent audiometry, 28% had a degree of hearing loss. More than two-thirds of English soldiers who have returned from Afghanistan, from injuries suffered severe and permanent hearing loss [5]. Animal experiments showed that 60 hours after acoustic trauma injury, the number of morphologically damaged inner ear sensory cells was lower in animals treated with HBO than in those treated without HBO [17, 18]. The best therapeutic effect on noise-induced hearing loss was obtained with a combination of HBO and prednisolone [19]. Animal studies in rats [20], pigs [18], and chickens [21] all showed that the HBO-treated group had a significantly reduced signal-to-noise ratio. Also in human studies, victims of acoustic trauma in military operations were treated with HBO [22]. There was a significant improvement in hearing loss. Therapeutic results confirmed that 65% of patients who were not treated with various methods had improved hearing [23]. Based on studies performed at different times and conditions of hearing loss compared to other treatments, it can be concluded that HBO is recommended within 3 months after the onset of the disorder, and treatment with it is guaranteed [24].

Soft tissue infection

Soft-tissue infections, occur after trauma and around the foreign body, and even spontaneously [25]. A common factor, tissue hypoxia that suppresses the immune defense mechanisms [26]. In animal models (mice, rats, rabbits), mortality was significantly lower during treatment with antibiotics and HBO. But (depending on the specific type of bacteria) seen a series of adverse effects was treated with HBO, the streptococcal infection worsened [27]. The level of evidence for soft tissue infections and HBO is low. There are only case reports and retrospective studies, and no RCTs are available. Almost all patients studied were endangered hosts [28-30].

In the study of war-related organ injuries including type 3 combat fractures and the description of the effect of HBOT on wound healing and complications of infection, it was shown that the reduction of infectious complications in patients who have used HBOT in the treatment process (31). Recent studies aimed at determining the effect of HBOT in the treatment of acute surgical wounds and trauma have shown a lack of quality clinical trial studies and pointed to the need for further studies [32-34].

Crush Injury

Crushing causes severe tissue damage and calls into question tissue survival. These injuries lead to local hypoxia. Ischemia, on the other hand, causes edema due to direct vascular trauma, fluid secretion, or compartment syndrome. Edema is either vasogenic or cytogenic and increases the distance of oxygen delivery to the cells. Edema also leads to capillary collapse, thereby increasing the severity of hypoxia [35]. The main purpose of using hyperbaric oxygen in crushing injuries is to cause excessive tissue oxidation.

Animal models (rodents, dogs) Crush injury studies have shown significant effects of HBO treatment [36]. HBO also regulates inflammatory gene expression in endothelial cells and can reduce the expression of apoptosis.

In human studies, most data are obtained from case reports or series of up to 35 patients. And there is only one RCT that compares crush injuries with and without HBO treatment [37], which improved treatment and significantly reduced surgery. Patients over the age of 40, in particular, benefited greatly from HBO treatment. From the available data, experts conclude that the adjuvant use of HBO in crushing injuries may lead to a favorable outcome for selected patients [34, 38].

Burns

Burns are followed by hypoxia and tissue ischemia [39], which increase edema with loss of capillary wall integrity (endothelial cell contraction). This fluid loss, by changing the oncotic pressure gradient in the capillary wall, further reduces the intra-capillary fluid pressure and thus increases stasis [40]. As a result, areas of second-degree superficial burnt tissue (minor burns), develop in the first 24 hours after the burn, it progresses to a deep second or third-degree burn, which requires early surgery and a transplant to heal [41].

In all of these pathophysiological mechanisms, hypoxia plays a pivotal role. Oxygenation of ischemic tissues should be performed rapidly and in large volumes, to reduce tissue damage with ischemic-reperfusion. Hyperbaric oxygenation is the only treatment that can ensure that the treatment is successful [42, 43].

Several reports show the help of HBOT in the treatment of severe burns [44]. The use of HBOT in severe burns in a war scene may reduce the need for surgery and length of hospital stay [45], and possibly reduce mortality [46].

When soft tissues (such as skin and muscle) are burned, blood flow to the affected area is severely reduced. This causes the area to swell, and the swelling spreads from the affected area in all directions. The swelling may reach deep into the muscles and surrounding skin, causing more damage than the original injury. HBO should be used very soon to limit initial debridement and gradual tissue destruction [47].

The theoretical beneficial effect of HBOT on burn wounds is in the antibacterial effects of possible infections, in reducing edema and systemic inflammatory response, in limiting the size of burned tissue, and in increasing collagen formation. It seems that the best results from starting hyperbaric treatment in the first hours of injury. However, studies indicate a low and unclear role of HBOT in the management of severe burns. A randomized study supports the use of HBOT to evaluate the potential positive effects of HBOT on experimental burn wound healing [48]. In this study, the authors demonstrated a beneficial effect on HBOT wound healing and hypothesized that such an effect would be determined by reducing edema and maintaining microcirculation. Although the quantity and quality of evidence-based studies on the potential benefits of HBOT in patients with burns are poor, its potential use in medicine, war is worthy of further investigation. To achieve the best result, careful selection and screening of patients are recommended [47].

Special attention has been paid to the use of HBO in respiratory injuries. There is currently concern that HBO may worsen lung damage, especially in patients with high levels of inhaled O_2 [49]. Studies have not reported any evidence of oxidative stress in HBO-treated burn patients who used lipid peroxidation exhalation products as a symptom [50].

However, a series of compelling prospective and retrospective studies have been published [47, 51] that show less need for surgery, reduced mortality, shorter hospital stays, and reduced treatment costs when using HBO concomitantly with conventional therapy. But so far no prospective placebo-controlled trials have been published that explicitly prove the effectiveness of HBO treatment [52, 53]. Therefore, acceptance of HBO as a valuable adjunctive therapy is limited to those burn centers that can provide early treatment of HBO without adding additional risks (infectious, hemodynamic) to the patient's condition [54, 55].

Frostbite

Frostbite-like thermal burns a profound impact on local microcirculation that it can be cold or an injury or an acute and prolonged exposure to cold be defined. It has been shown that after heating, a long-term damage phase occurs, which is very similar to the ischemia-reperfusion injury observed in thermal burns. At least, in theory, hyperbaric oxygen therapy could have the following benefits in frostbite injury.

Animal studies (especially rabbit studies) have been conducted sporadically over different years [56, 57], with each study showing different results [58-60]. These different results suggest that deep and rapid freezing damage can indicate several important differences in pathogenesis and tissue damage from slow to moderate freezing.

The experiments carried out on animals, the early application of HBO during or immediately after the heat re-use. Some sporadic case reports suggest that HBO may be helpful, even long after warming up. Because these are uncontrolled and isolated reports, the evidence supporting these claims is not very strong. In 2001, he reported a case in which HBO was used after only 4 days for a young boy who had both hands frozen, and was able to save all his fingers [61]. Similarly, cases have been reported, 12 and 22 days after frost damage and the use of HBO led to the rescue of the individual fingers [62, 63].

Although the experience is relatively limited because HBO is generally not recognized as a complementary treatment standard for frostbite; clinically, HBO appears to provide early, good and rapid separation of growing tissue from non-growing tissue. MR angiography, one week after the onset of the injury, looks promising in estimating the likelihood of resuscitation of the fingers [64].

Spinal cord injury

Many studies have examined the mechanism of action of HBOT in SCI [65, 66]. Some studies have shown the protective effect of HBOT in the treatment of SCI [67, 68] and others recommended a review of the care process [66]. The number of treatment sessions for patients with spinal cord injuries is determined by the patient's condition and response to treatment, but according to studies, at least 30 sessions of standard HBO treatment 5 sessions per week were recommended to begin treatment [69].

Carbon monoxide poisoning

Because lipid peroxidation is an important aspect of CO-induced neuronal damage, inhibition of neutrophil O_2 integrins at the cellular level by HBO therapy has been identified as a significant advantage of that treatment. HBO relieves cerebral edema through vasoconstriction [70]. HBO therapy is unique in increasing oxygen delivery while causing blood vessels to constrict.

Experimental studies have shown that HBO treatment restores mitochondrial oxidative metabolism in addition to eliminating tissue hypoxia [71] and prevent lipid peroxidation [72] and prevents endothelial leukocyte adhesion [73]. Although many studies have talked about the healing process and preventing the disease from getting worse [74-76], In some studies, the authors failed to demonstrate a significant advantage of an HBO treatment session over NBO treatment in patients with loss of consciousness. Similarly, treatment with two sessions of HBO showed no advantage over one session of HBO in patients who were in a coma [77].

Decompression sickness (DCS)

Decompression sickness (DCS) occurs when atmospheric pressure decreases too rapidly. During this syndrome, bubbles of inert gas dissolved in blood or tissues lead to blood supply blockage, direct mechanical damage, or biochemical actions. DCS can be expected after scuba diving, ascent with flying, or hypobaric or hyperbaric exposure [78, 79].

The endothelium of vessels can be injured by the bubbles causing DCS. This damage induces platelet aggregation, lipoproteins denaturation, and leukocytes activation. These events eventually lead to capillary leaks and proinflammatory events [80, 81].

Hyperbaric oxygen therapy (HBOT) by using an oxygen gradient and also through pressure is ale to reduce the size of the bubbles. According to Boyle's law, pressure increases can decrease the volume of the bubble. The bubble causing DCS is thought to be composed of nitrogen.

In the process of DCS, when a tissue ascends to a decreased atmospheric pressure, bubbles derived from nitrogen seep out of blood, tissue, or both. By breathing 100% oxygen in HBOT, the blood becomes rich in oxygen and poor in nitrogen that leads to a gradient of nitrogen between the blood and the bubble. So nitrogen goes from the bubble into the bloodstream which makes the bubble smaller [79].

Recompression is the choice of treatment. The greatest success from recompression, as the definitive treatment, occurs when treatment is done as soon as possible but no exclusionary time from symptom onset has been established [79, 81]. Assessment patient's symptom response to therapy determines the time a patient is kept at 60 or 30 fsw [82].

Recovery therapy

Military response is now accepted around the world to assist civil society in natural disasters. Most of the time, military support is provided only in large-scale disasters. In contrast, local resource capacity can be used in small-scale disasters.

On the other hand, due to the proposed vascular etiology, many other treatment modalities were proposed and experimentally tested. Examples of treatments are blood flow-promoting agents, dextran, vasodilators, and pentoxifylline. However, many of these studies have did not show effectiveness within the clinical setting [83-87].

According to some authors, contraction of the prostheses caused by HBOT treatment reduces tissue edema and secretion of acute post-traumatic inflammatory factors, which can have an analgesic effect on acute pain [88, 89]. So we conclude that, at least from a pathophysiological point of view, HBO should be started as soon as possible, so HBO delayed effects can be considered reasonable, even so, it is impossible to define a period in which HBO can be considered anything more than a tool [90].

Recommendations

For future studies, we recommend starting therapy as early as possible, preferably within 48 h and to use combination therapy. Furthermore, we recommend investigating the relationship between the effects of HBO and age, sex, and underlying disease. In future studies, randomization and having a control group also seem necessary.

CONCLUSIONS

HBOT has been used quite extensively in the last couple of decades. Even though most studies were not randomized controlled trials, we think that based on the number of studies showing a positive effect, HBOT should be discussed with patients (shared decision making) as optional therapy.

This narrative review has described the rationale and clinical evidence for equipping medical centers with HBO systems, especially in military areas. Equipping military hospitals with this treatment system can perform the first stage of treatment for the individual before the transfer and speed up the treatment process, especially in combination therapies.

Therefore, centers can be classified based on belonging to different categories of hospitals, and for each pathology, a suitable hospital category can be defined. Given that so far no formal coordination has taken place between the military hyperbaric centers of different countries, interoperability facilitated the organization of cooperation in the field of multinational operations.

We emphasize international cooperation on the applications of hyperbaric medicine in military medicine. At the International Congress of Military Medicine (ICCM) held in Iran in 2018, a panel on hyperbaric medicine was held with the participation of hyperbaric medical professors from the participating countries. In this research panel, Dr. Shahram Oliaei, hyperbaric medical researcher, emphasized research and educational cooperation to further coordinate the hyperbaric medical centers of the member countries.

Towards an integrated medical system for radiological medical imaging investigations

Lidia Dobrescu[1], Silviu Stanciu[2], Cezar Pleșca[3], Armand Ropot[3]

Abstract: *The continuously increasing number of medical investigations using radiological methods imposes the strong necessity of informing patients about benefits and risks regarding radiation absorbed doses. Tracking the radiation doses absorbed by patients must be a future challenge of any medical system. The effective doses received by patients in many types of medical investigations must be calculated, transformed, recorded and cumulated. Doctors and patients must be very responsible in prescribing or demanding new radiological medical investigations. Radiological standards, legislation, guidelines, programmers and practice supervised by international commissions on radiology protection must include new specific measures for patients' cumulated doses. A pilot Romanian project had tried to accomplish some of these tasks.*

INTRODUCTION

Radiation is commonly associated with nuclear accidents or modern irradiative artificial sources such as: mobile phones, great antennas, satellites, food irradiation, and radioactive building materials.

Generally, radiation is associated with all kind of human activities.

As a huge surprise, in fact, radiation is quite a natural phenomenon in our lives. There are many radioactive substances in air, water and soil that are called natural background radiation. During a long airplane flight one can also receive an important radiation dose. Typically doses from natural sources are measured in mSv. The Sievert (Sv) is the International System of Units (SI) derived unit for radiation dose.

There are many other different units for absorbed radiation and transformations can be made in order to compare them.

A recent United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) publication [1] estimates worldwide distribution of radiation exposure:

- 13% from cosmic sources
- 16% from soil
- 9% from food
- 20% from medical investigations
- 42% from radon sources

Radon-222 is a radionuclide in the form of a gas that normally emanates from the soil. Radon is a colorless,

---

[2] Carol Davila Central University Emergency Military Hospital, Bucharest
[3] S.C. CERTSIGN S.A. Bucharest

odorless, radioactive gas. Most exposure to radon comes from being indoors in buildings. A strong interaction between smoking and radon has been proven, so radon is considered as a primary cause of lung cancer, smokers being more vulnerable [2]. There are no widely available medical tests to measure radon exposure. So radon belongs to natural sources of radiation.

The increased doses of radiation in our climate and habitat is surveyed by national or international organizations, there are standards, policies and strategies for general radiation protection.

International commissions on radiology protection are worldwide active for radiological standards, legislation, guidelines, programmers, and practice.

The United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) highlights the levels and effects of exposure to ionizing radiation [1].

The International Commission on Radiological Protection (ICRP) has published a lot of reports on generally human protection and the specific protection of patients exposed to ionizing radiation [3].

In Romania, CNCAN is the national competent authority in nuclear field “having responsibilities of regulation, authorization and control stipulated in this Law is the National Commission for Nuclear Activities Control, public institution of national interest, legal entity, with the head office in Bucharest, being headed by a President having the rank of State Secretary, coordinated by the Prime Minister [4].

RADIOLOGICAL MEDICAL INVESTIGATIONS

Medical imaging is a complex process of visualization of the interior of a human body. A lot of techniques and engineering tools are used in order to obtain a visual representation:

- Radiology using X-rays;
- Computed Tomography (CT scan) using also uses special X-ray equipment;
- Nuclear medicine, using internal radioactive substances including scintigraphy that uses radio-isotopes travelling to organs, positron emission tomography (PET) or Single-photon emission computed tomography (SPECT) ;
- Mammography as a specific type of breast imaging that uses low-dose x-rays;
- Magnetic resonance imaging using the property of hydrogen atoms from human body to absorb or emit radiofrequency energy when placed in an external magnetic field;
- Medical ultrasonography or ultrasound, a diagnostic imaging technique based on the application of ultrasound;
- Endoscopy using an instrument inserted in the human organ;
- Thermography, using thermographic cameras and infrared imaging techniques;
- Elastography;
- Tactile imaging or mechanical imaging.

Only the first four investigations imply radiological methods in medical investigations. The last ones do not imply radiological risks, even there are scientific debates on SAR (specific absorption rate) as a dosimetric quantity for Electromagnetic Fields bio effects [5].

Patient exposure to ionizing radiation can be made externally, internally nor both. CTs doses are usually externally absorbed, while in angiography, fluoroscopy or scintigraphy investigations, a radioactive substance is ingested. Contrast media are also used on radiography and CT to visualize vessels or tissues. Iodine is a modern intravenous contrast agent, but barium is also used. Usually iodine contrast media is used intravenously, it can also be used intra arterially. Barium sulfate is usually swallowed. Magnetic Resonance Imaging or CTs also use contrast agents.

Differences between exposure and contamination can also be debated [6]. Exposure to a radiation source does not imply that this person becomes a new radioactive source. Contamination incorporates the radioactive agent in the body, such as in thyroid gland.

Exposure to X- rays increases the future incidence of cancer, but quantitative models predicting the level of risk are still not worldwide accepted. Different methods for radiation risk calculus are available. The

linear no-threshold (LNT) model assumes the proportionality between cancer risks versus absorbed dose. The relationship between dose and DNA damage is considered linear. The International Commission on Radiological Protection (ICRP) recommends the use of the LNT model [7].

Significant uncertainties are related to dose assessment, low dose and low dose-rate extrapolation approaches, transfer of risks from a population for which health effects data are available to one for which such data are not available [8]. Adaptive responses of human cells have also been observed at low doses [9].

Classical radiographies, computed tomographies (CTs) and scintigraphies are worldwide used medical radiological investigations that expose the patients to significant doses of radiation.

The actual volume of medical prescription, the contrast substances used in order to increase their accuracy, the overlapped investigations are general causes for a strong increasing of the cumulative radiation dose absorbed by patients. Patients and doctors usually excess in demanding, using and prescribing medical investigations in spite of harmful effects associated with radiation delivery.

The prescribed medical investigations total volume, starting from dental radiographies and ending at multiple regions CT scans prove a gap in monitoring and tracking of the cumulative radiation doses in many health services all over the world. The received radiation doses by patients are quit impossible to be cumulated in spite of the fact that in our modern world, 20 % of absorbed radiation dose is due to medical investigation.

The patients travel from one hospital to another, all over the country or all over the world.

An integrated system must be implemented. In order to cumulate all the absorbed doses by a patient in different types of radiological investigations, the doses measurement units must be the same and the recorded doses must be kept together in a single patient monitoring unit.

RADIATION DOSE RISK AND DIAGNOSTIC BENEFIT [10]

The treating physician and the radiologist can prescribe and carry out radiological imaging procedures. Several objectives and subjective elements are implied in a prescription:

- Medical request
- Imaging investigation algorithm
- The personal experience of the examiner
- Patient history
- The results of any other previous investigations

All the time a correct judgment concerning the benefit/risk ratio must be performed. Medicine and the radiation risks knowledge must be well handled. The aim of managing radiation exposure is to minimize the irradiative risk without sacrificing, or unduly limiting, the obvious benefits in the prevention, diagnosis and also in effective cure of diseases (optimization).

When too little radiation is used for diagnosis or therapy there is an increase in risk. Too low an amount of radiation in diagnosis will result in an image that does not have enough information to make a correct diagnosis. There are several ways that will minimize the risk without sacrificing the valuable information that can be obtained for patients' benefit. A possible measure is to carefully justify the examination before sending a patient to the radiologist or nuclear medicine physician. Repetition should be avoided in recently investigations performed into another clinic or hospital. An investigation may be seen as a useful one if its outcome – positive or negative – influences management of the patient. Another factor, which potentially adds to usefulness of the investigation, is strengthening confidence in the diagnosis. Most common examples of unjustified examinations include: routine chest radiography at admission to a hospital or before surgery in absence of symptoms indicating cardiac or pulmonary involvement (or insufficiency); skull radiography in asymptomatic subjects of accidents; lower sacrolumbal radiography in stable degenerative condition of the spine in the 5th or later decade of life, but there are of course many others [11]. From medical experience, the diagnosis

benefit is a priority. For a lung Rx examination any suspected image is repeated or supplementary investigated in a Computed Tomography.

Many times, the personal experience of the radiologist is the dominant factor in high radiation doses investigations:

- urgent exam such as trauma and polytrauma, fractured skull or spine where CT exams are a real benefit for the patient and an economic benefit for the hospital. They can shorten the patient’s hospital stay.
- scintigraphic investigation in thyroid diseases
- repeated mammography
- bone disease with seemingly benign tumors requiring an examination for differential diagnosis.

RADIATION MEASUREMENT UNITS

„The International Commission on Radiological Protection (ICRP) recommends that the public limit of artificial irradiation should not exceed an average of 1 mSv effective dose per year, not including medical and occupational exposures. ICRP limits for occupational workers are 20 mSv per year, averaged over defined periods of five years, with the further provision that the dose should not exceed 50 mSv in any single year“ [12].

The Sievert (Sv) is a derived unit in the International System of Units (SI) used for equivalent absorbed radiation dose measurement. This must be the central unit of a tracking medical system.

There are many different units for absorbed radiation used on a large scale. Becquerel (Bq) and Curie (Ci) as SI units are used for released radioactivity, while Coulomb/Kilogram (C/kg) and Roentgen (R) are used for the dose travelling through the air, Gray (Gy) and Rad, used with quantities of absorbed dose. A lot of Internet sites provide convertors between them.

The biological effects of the absorbed amount of radiation can be described with Roentgen equivalent man (rem) and Sievert (Sv). They are specific measurement units.

The Sievert can better describe the effective equivalent dose absorbed by biological tissues while the Gray can describe the absorbed dose of any material.

Table 1: Radiation Measurement Units

Type	Measurement unit		
Released radioactivity	Curie (Ci)	Non-SI	**1 curie = 3.7×10^{10} radioactive decays per second**
	Becquerels (Bq)	SI unit Derived	One becquerel represents the activity of a quantity of radioactive material in which one nucleus decays per second – **$1\ Bq = 1\ s^{-1}$**
Dose travelling through air (Exposure)	Coulomb/Kilogram (C/kg)	SI unit	**1 C/kg = 3876 R**
	Roentgen (R)	Non-SI	**1 C/kg = 3876 R**
Absorbed Radiation dose	Gray (Gy)	SI unit Derived	It is defined as the absorption of one joule of radiation energy per kilogram of matter **$1Gy=1J/Kg=1m^2/s^2$**
	Rad	Deprecated, replaced by the Gray	**1 rad = 0.01 Gy = 0.01 J/kg**
Dose equivalent (the biological effects of the absorbed amount of radiation)	Röntgen equivalent man (rem)	Non-SI	**1 rem=0,01Sv** **1 mrem/h = 8766 mrem/yr**
	Sievert (Sv)	SI unit Derived	represents the equivalent biological effect of the deposit of a joule of radiation energy in a kilogram of human tissue

Modern radiological apparatus for computerized tomographies or scintigraphies can provide the radiation doses during a particular investigation, but the recorded doses’ types and the radiation

measurement units in different types of investigations are not the same.

In the classic radiological investigation an important topic for data management is the measurement and the calculation of radiation dose expressed in Dose area product (DAP), expressed in (Gy*cm2). The dose length product (DLP) was chosen as input data for the system in CTs investigations and it is expressed in mGy*cm. The DLP must be converted to mSv in order to unify the results.

REQUIREMENTS OF A DESIGNED TRACKING SYSTEM

A tracking proposed system must include computers, smartcards for storing data and suitable software applications for recording, retrieving and alert. The effective doses received by patients must be unified and cumulated.

The system provides the replication of the information stored in central databases, local databases and patient cards to cover all the following possible situations:

- The patient goes to the doctor without the patient card. In this case, the system provides the data corresponding to the patient based on the local database, if the patient has been investigated in that hospital unit; if the patient is new, the system must provide the data from the central database to the local database, so as to take the optimal decision in recommending the type of investigation. After the investigation, the system must store the new local database accumulated radiation dose to the patient, the information arriving in the central database. Later, when the patient goes to the doctor for further investigations with the card, the system must ensure synchronization between the information stored on the card and information stored in the local and central database.
- The patient goes to the doctor with no card and the hospital unit’s information system does not have access to the central database (ex: for mobile laboratories). If the local database contains the information corresponding to the patient, the doctor must be able to use them for recommending a particular type of investigation. After the investigation, the system must store in the local database the new radiation doses accumulated by the patient. Later, when the local system can access the central system, the information corresponding to the patient must be synchronized between the two databases.
- The patient presents the card to the doctor but the doctor does not have access to any database (local or central). In this case the doctor, using a computer with a card reader can access the history of investigations and the doses received by the patient, as the current cumulative dose calculated and can recommend the most appropriate investigation. After investigation, the appropriate dose must be recorded on the patient’s card and next time when the patient goes to the doctor with the card, this information must be stored in both in the local and the central database.

Additionally the system provides applications for:

- Viewing in real time the history of investigations, of the doses delivered to the patient and of the current cumulative calculated dose expressed in mSv.
- Aiding the medical staff in taking the adequate decisions regarding the indication of investigations according to the current calculated cumulative doses and the maximum doses allowed for the risk and age groups.
- Performing of various periodic reports in order to take different types of decisions related with the existing radioprotection rules.

The proposed system includes the following modules:
a) Applications running on smart cards, called on card applications.
b) Off-card applications that are running on medical stations. They include smart card readers and writers in order to record and retrieve the information about the type of investigations and the specific emitted doses
c) A data base records all the necessary information in order to replicate a lost or destroyed card but also this database must provide the possibility of collecting data about the patients on several criteria, it must provide the possibility of standard or customized reports’ creation.
d) The security solutions such as public key infrastructure PKI in order to achieve a high level of

security of recording and retrieving data. A public-key infrastructure (PKI) is a set of hardware, software, people, policies, and procedures needed to create, manage, distribute, use, store, and revoke digital certificates. A PKI establishes and maintains a trustworthy networking environment by providing key and certificate management services that enable encryption and digital signature capabilities across applications — all in a manner that is transparent and easy to use. Digital certificates are electronic credentials that are used to assert the online identities of individuals, computers and other entities on a network. They are issued by certification authorities (CAs) that must validate the identity of the certificate-holder both before the certificate is issued and when the certificate is used.

The entire system must be designed around the two types of cards: the patients' cards and the medical cards and it ensure many requirements ensuring secured communications.

Two different data flows must be implemented:

- Electronic cards flow management that includes: smart cards issuance, their renewal in case of loss, damage or theft.
- Operational cards flow management including: patients and doctors authentication using unique PINs.

DESIGNED SYSTEM

A Romanian pilot study has been implemented the International System of Units uses the Sievert (Sv) as a derived unit in order to estimate the effective dose.

The new Romanian system is based on smart cards and Public Key Infrastructure and its structure is represented in figure 1. The system was implemented in Dr. Carol Davila Central Military Universitary Emergency Hospital, Bucharest, Romania.

The whole designed system and software application was the main result of the 187/2012 SRSPIRIM project in a Romanian National Partnerships Program, Collaborative Applied Research Projects – PCCA 2.

The system includes the following components:

- smart cards dedicated to patients: Citizen Radiation Safety Card (CRSC) and
- professional Radiation Safety Card (PRSC), designed for medical and investigation laboratories personnel. Among the last ones, one or more Administrator Radiation Cards are also designed and used in order to enroll patients in the application.

A common patient card and a doctor card are shown

in Figure 2.

The hardware part of the system consists in computers, smart cards and card readers in order to record and retrieve the information about the type of investigations and the specific emitted doses.

The software includes a data base that records the commonly information on doctors, patients, types of medical procedures but also designed applications in order to replicate a lost or destroyed card.

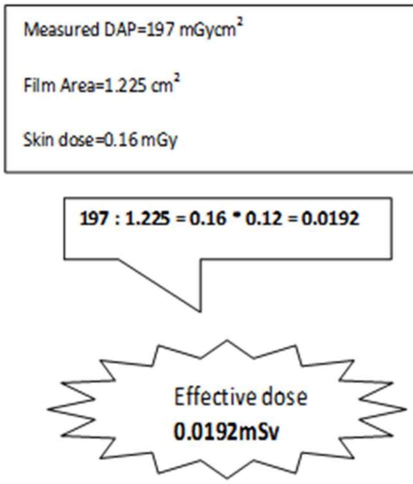
This database provides the possibility of collecting data about the patients on designed criteria and future designed reports. Central database diagram, containing the recorded medical information are stored in many tables. A part of the design of the complex relationships between these tables is presented in Figure 3.

The security solutions include a Public Key

Infrastructure base (PKI), in order to achieve a high level of security of recording and retrieving data. A public-key infrastructure (PKI) is a set of hardware, software, people, policies, and procedures needed to create, manage, distribute, use, store, and revoke digital certificates. A PKI establishes and maintains a trustworthy networking environment by providing key and certificate management services that enable encryption and digital signature capabilities across applications — all in a manner that is transparent and easy to use. The application ensures a secured authentication of doctors and patients using digital certificates and cryptographic hardware. The whole logic application is stored in the central server. The clients use the minimum functional software. The applications users have access through a web browser. The system uses cryptographic libraries FIPS 140-2 or CC EAL4. The keys are RSA 1024 bits minimum length. The cryptographic hardware must support PKCS#11, PKCS#15 and Microsoft CryptoAPI. The cryptographic hardware must ensure the recovery of the cryptographic context. The certification system ensures roll–over facilities. The PKI system has an own relational database storing all the emitted certificates.

Figure 4: Effective dose calculus in radiological investigations



EXPERIMENTAL IMPLEMENTING

In the classic radiological investigation the calculus for radiation dose uses Dose Area Product (DAP), expressed in (Gy*cm^2) as an indicator of the total risk of inducing cancer. It also has the advantages of being easily measured, with a DAP meter on the X-ray set. In order to obtain the effective dose measured in Sv, the DAP is divided by the film area and then it is multiplied by the tissue factor [13] as shown in Figure 4. A sensible situation was determined by CT-s registered dose. More related CT radiation doses are available on CT consoles. Dose length Product DLP was chosen as input data for the system in CTs investigations but the required reported data is the effective dose. Conversion factors were used. The conversion factors can slightly vary from different manufacturers. Conversion factors for normalized effective dose per DLP depend only on the region of the body being scanned. All CT manufacturers provide tables with such conversion factors.

Conversion factors are also available for children of various ages, but this project does not include children [14]. Conversion problems were detected for multiple CT scans in one single examination, because more DLP are measured in the same examination and recording them becomes a long procedure.

EXPERIMENTAL RESULTS

Different studies were performed.
During a starting one month study in the hospital, the maximum cumulative dose has been overpass The CT exams are the most concerning prescribed imaging investigations that can lead to high cumulative doses.

The initially Figure 5 reveals some aspects from the initial study at the beginning of the project. The initial proposed threshold radiation dose of 20 mSv was frequently over passed and maybe a higher dose may be accepted for medical investigations in the future.

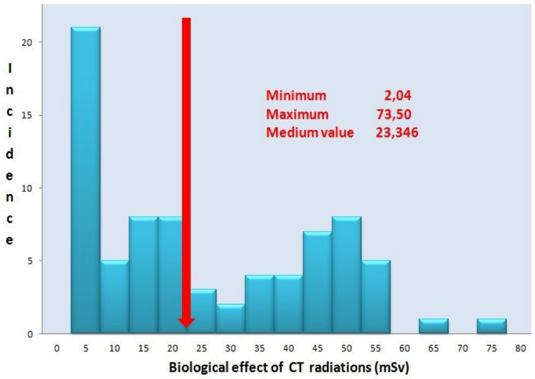
During a three years study in the hospital, different studies were performed.

The database contains 1125 records with 333 patients. From these records 42 patients were rejected in the final analysis because incomplete data.

These records contain all the investigations performed and all patients.

A lot of patients were examined in more than one investigation, so the system enrolled only 291 unique patients.

Figure 5: Cumulative radiation doses received by patients in the initial study



The recorded cumulated effective doses are shown in figure 6 and their distribution on decades is shown in figure 7.

Figure 6: Recorded doses in the project

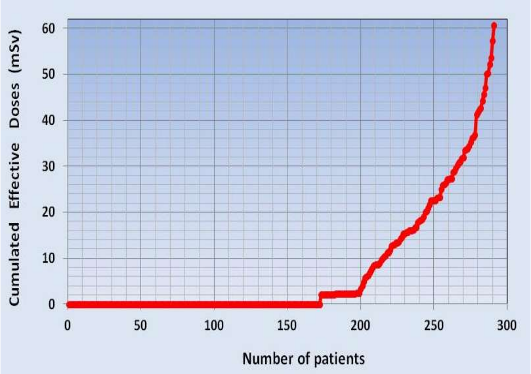


Figure 7: Recorded doses on decades

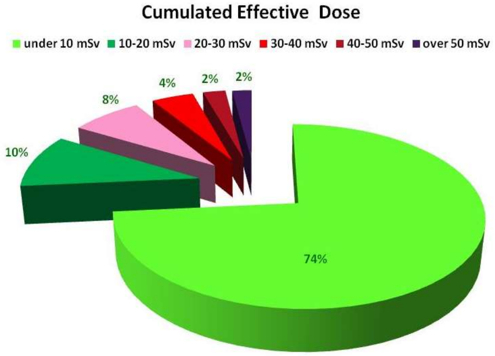

From these 291 patients, shown in figure 8 by gender, many of them have performed multiple investigations as in figure 9 and from them, in 47 cases, the received cumulated dose exceed the 20 mSv threshold dose, meaning 16,5% of cases.

Figure 8: Patients recorded in the project

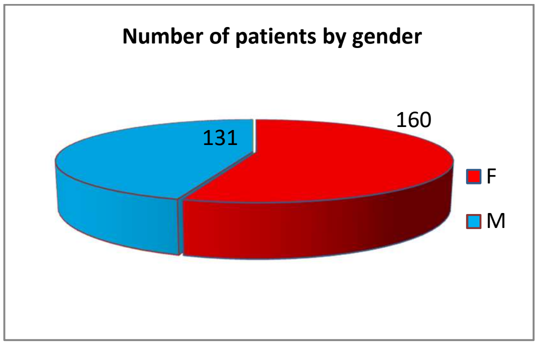

Figure 9: Patients recorded in the project

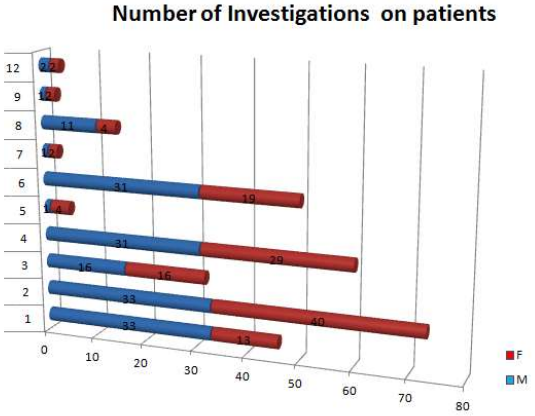

ACKNOWLEDGMENT

The results were obtained from the SRSPIRIM project 187/2012, in Romanian Partnerships Program, Collaborative Applied Research Projects Subprogram. The authors wish to address thanks to all the persons involved in this project for their support, work and ideas.

REVIEW ARTICLE

Article received on November 12, 2016 and accepted for publishing on March 2, 2017.

General considerations regarding the infections with the Escherichia coli pathogen

Marius Necşulescu[1], Bogdan-Ioan Coculescu[1,2], Simona Bicheru[1], Diana Popescu[1], Lucia Ionescu[1], Gabriela Dumitrescu[1], Viorel Ordeanu[1,2]

Abstract: *Escherichia coli is the species of the genus Escherichia with the greatest epidemiological impact. Escherichia coli infections are found mainly in places with poor hygiene; the infants with ages between 1 and 3 years old are included in the category with the highest risk. It is a "fecal-oral" transmission mechanism as a result of consumption of contaminated food or water, or by "dirty hands". The foods most commonly implicated in the transmission of the infection are unpasteurized milk and milk products, beef, especially the one insufficiently cooked, unpasteurized fruit juice, lettuce and insufficiently washed vegetables. The disease has been reported worldwide, being described numerous episodes of infection with Escherichia coli that caused multiple illnesses and deaths. Escherichia coli has three types of antigens: antigen "O" (somatic), antigen "H" (flagella) and antigen "K" (capsular). Clinical manifestations are present in the form of non-specific diarrhea, a dysentery form of enteritis, choleriform enteritis, hemorrhagic colitis and hemolytic uremic syndrome (HUS). The Escherichia coli infection diagnosis is made by identifying the etiologic agent and/or by highlighting the VTI toxin in the feces. The treatment consists in precautionary antibiotherapy, hydrodynamics and electrolyte rebalancing, blood transfusions and dialysis, if in the case of renal failure. The prevention of infections with Escherichia coli is achieved by personal hygiene, food hygiene and work hygiene.*

Keywords: *Escherichia coli, infection, toxin, treatment, hygiene*

INTRODUCTION

Escherichia coli is the species of Enterobacteriaceae, of the genus Escherichia, with the greatest epidemiological impact. Escherichia coli infections are found mainly in places with poor hygiene; infants are included in the category with the highest risk. Also, adults can develop severe forms of infections, especially in regions where underdevelopment, poverty and lack of hygiene are the dominant picture.

The disease can occur in particular through the "fecal-oral" transmission mechanism as a result of consumption of contaminated food or water, or by "dirty hands". The foods most commonly implicated in the transmission of the infection are unpasteurized milk and milk products, beef, especially the one insufficiently cooked, unpasteurized fruit juice, lettuce

[2] Titu Maiorescu University, Bucharest

and insufficiently washed vegetables. Processing raw food can contaminate kitchen utensils, especially if these are not separately used for each food category and are not cleaned between uses. Contamination can occur through contact with carrier animals, if the basic rules of personal hygiene are not complied with, such as washing hands with soap and water.

In recent years, in nearly all parts of the world have been reported numerous episodes of infection with Escherichia coli, resulting in numerous illnesses and even deaths. We recall the tragedy of Walkerton (Ontario/Canada), when approximately 5,000 people from the community showed symptoms specific to the digestive infection, the etiological agent being Escherichia coli [1]. In 2011, in Germany broke one of the largest outbreaks of acute gastroenteritis with hemolytic uremic syndrome (HUS) caused by the E. coli O104: H4 strain (German hemolytic uremic syndrome/ enterohemorrhagic E. coli - GHUSEC). The outbreak has had an unusual epidemiological origin only partially resolved. Investigations conducted by authorities showed that the illnesses occurred amid the consumption of contaminated water by agricultural runoff into a water well and subsequently there was the groundwater contamination [2].

The latest outbreak of the infection with Escherichia coli is evolving in Romania with this disease being contracted by 12 children (so far), aged between 1 and 3 years, all coming from localities in Argeș County.

The particularly severe infection resulted in the death of 3 children and even though the competent bodies through their health authorities have sought to find the source of the outbreak, they have not been able until now to find the source of the infection.

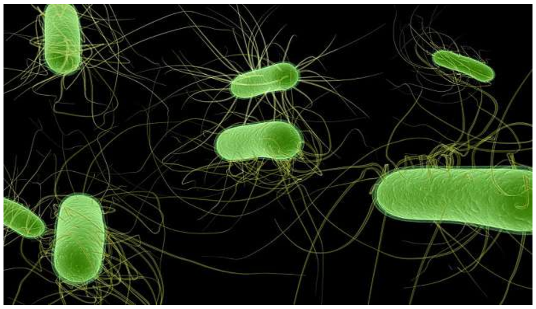
After the latest information, this seems to have been about a false "outbreak of diarrheal disease with uremic syndrome"; in reality the infectious etiology is varied, as confirmed by the Cantacuzino Institute.

In conclusion, due to the lack of a common source for the contagion, there cannot be a question of an epidemic or outbreak as the cases are isolated; however, due to the media pressure the incident could be termed as a "media outbreak".

ETIOLOGY

The genus Escherichia is of the Enterobacteriaceae family which comprises of 44 genera, 25 of which are found in human pathology. Most of these genres include commensal bacteria very abundant in nature (soil, water, etc.) [3], their natural habitat being the gastrointestinal tract of humans and warm-blooded animals, their feces containing more than 1010 enterobacteria/gram [4]. The constant presence of Escherichia coli strains in human and animal intestines and implicitly in the feces, determined that this bacterium represents the indicator of fecal pollution of the environment, especially of the water. Within the genus, are known 6 species: Escherichia coli, Escherichia fergusonii, Escherichia hermannii, Escherichia vulneris, Escherichia albertii and Escherichia blattae, the latter being isolated due to the fact that it only comes from specific species of insects.

Figure 1: Escherichia coli
(http://www.telegraph.co.uk 620 × 387)

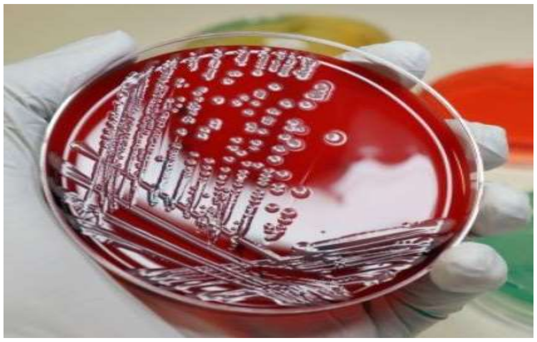


The most important representative of the genus is Escherichia coli, bacterium discovered by Austrian pediatrician Theodor Escherich. In 1886, after a hard clinical and laboratory activity he has presented at the Faculty of Medicine in Munich and subsequently published in Stuttgart, a monograph on the link between intestinal bacteria and the physiology of digestion in children entitled “Die Darmbakterien des Säuglings und ihre Beziehungen zur Physiologie der Verdauung” [5]. In 1919, Castellani and Chalmers proposed that the name of the isolated bacillus from the colon (Bacterium coli commune), by the renowned Austrian pediatrician Theodor Escherich be changed in Escherichia coli, in his honor, a name that was officially approved in 1958 [6]. Bacteria are present in the form of straight or slightly curved bacilli with rounded ends,

the presence of flagella and therefore the mobility being constant in most species (Figure 1). It has a size between 2-5 µm/0.5-1 µm and from a tinctorial point of view is Gram-negative.

It grows on simple culture media (simple glucose broth, nutrient agar and blood agar) developing specific Type S colonies, round, domed, shiny with a smooth surface (Figure 2) and regular edges or with dry R colonies with irregular edges.

Figure 2: Escherichia coli culture on blood agar (http://www.wzzm13.com 534 × 401)



Biochemically, is fermenting the glucose with the production of gas, it produces indol, β-galactosidase and ferments lactose, characteristic that is allowing the differentiation from other enterobacteriaceae. Escherichia coli has an aerobic or optionally anaerobic metabolism and develops at an optimum temperature of 370C and pH between 7.2-7.8 [7], but differs from other coliform bacteria by increasing to 44^{0}C.

THE ANTIGENIC STRUCTURE

Escherichia coli has three types of antigens that can be highlighted by serologic antigen-antibody reactions:

- The O antigen (somatic) represented by a lipopolysaccharide surface antigen, thermostable, common to all S forms of the Enterobacteriaceae family;
- The H antigen (flagella) is a proteinaceous antigen (flagellin), heat-labile present in bacteria flagella;
- The K antigen (capsular) which may be of a polysaccharide or protein (fimbriae) nature. The O and H antigens are transmitted via plasmids and can be found together with the K antigens that are chromosomally determined.

Up until now, have been identified more than 170 types of the O antigen, more than 50 types of H antigen, 90 types of K antigen and several types of fimbriae antigens (F antigens). Combining all these antigenic variants, results in more than 1,000 antigenic types of Escherichia coli.

CHARACTERISTICS OF PATHOGENICITY

Colonic microflora in healthy persons (normal intestinal microbiota) is dominated by strains of Escherichia coli that live in a symbiotic relationship with the host. These infections may occur only if the host is immunocompromised or when it crosses the intestinal barrier and reaches areas which would normally be sterile. There have also been described pathogenic strains of Escherichia coli which have an exacerbated virulence with the possibility of being able to multiply, triggering infectious processes in immunocompetent individuals. Currently, have been described 6 intestinal Escherichia coli pathotypes involved in the EPEC diarrheal syndrome (intestinal pathotypes) and a pathotype involved in extraintestinal infections (urinary tract infections, meningitis, septicemia), ExPEC [8]. It is the most common etiologic agent in urinary infections, being incriminated in over 80% of urinary tract infections (UTI).

The health of the host (diabetes, immunodeficiency, colon malformations, obstructive uropathies, etc) is predisposing factors for infection with Escherichia coli.

Intestinal pathotypes are: enteropathogenic Escherichia coli (EPEC), enterotoxigenic Escherichia coli (ETEC), enteroinvasive Escherichia coli (EIEC), verotoxin producing Escherichia coli (VTEC), enteroaggregative Escherichia coli (EAEC) and diffuse adhesion Escherichia coli (DAEC). Within the VTEC pathotype stands out, mainly to highlight the association with severe clinical manifestations (haemorrhagic colitis), the subset of strains of the enterohaemorrhagic Escherichia coli (EHEC), whose prototype is the O157: H7 serotype. The pathogenic Escherichia coli strains produce virulence factors that contribute and affect the processes undertaken at cell level in the host (the protein synthesis the cytoskeleton’s function, the cell division, ion secretion,

the mitochondrial function, apoptosis). Adhesins are adhesion structures located on the fimbriae/pili (P fimbriae from the uropathogenic strains of Escherichia coli, the CFA colonization factors from the ETEC strains) or on the surface of the outer bacteria membrane (Afa afimbriae adhesins from DAEC strains). They are important virulence factors that allow bacteria to colonize areas of the human body (the small intestine, the urinary tract, the vagina), in which it does not normally reside. Toxins are another category of virulence factors. Endotoxins are part of the structure of the outer membrane (the A lipid from the LPZ complex) and are present in all Gram-negative bacteria. Released upon the elimination of the bacterial cell wall, they manifest their toxic effects being involved in the occurrence of the fever and the toxic shock from septicemia. Exotoxins are synthesized in the processes of the bacterial metabolism, being specific to the various pathotypes of Escherichia coli. Currently, are known the structure and the functions of many toxins responsible for the pathogenicity of strains of Escherichia coli (e.g., heat-labile enterotoxin produced by ETEC strains, verotoxins 1 and 2 synthesized by the VTEC strains, enteroaggregative Escherichia coli heat-stable enterotoxin 1 of EAEC strains etc.). Another important component of the pathogenicity of the species is the capsule. The main role of the capsule is to inhibit the action of the serum complement and the phagocytosis, thus imparting bacterial resistance. The K1 capsular polysaccharide antigen is present in 80% of Escherichia coli strains, isolated from the cases of neonatal meningitis.

THE DISEASE

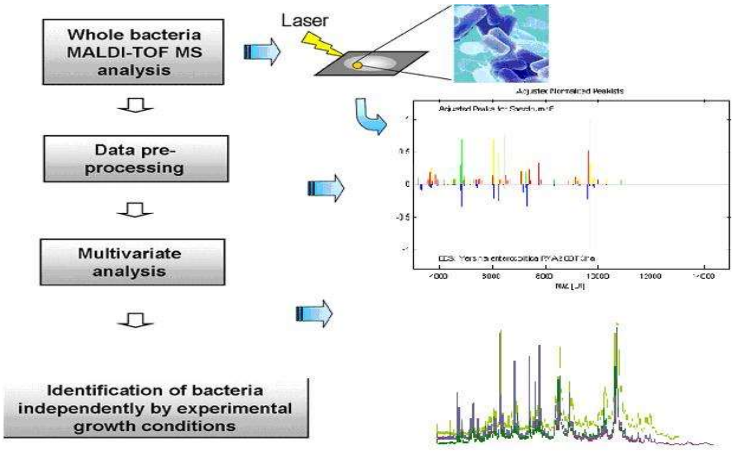
Most of the Escherichia coli outbreaks were associated with the presence of the O15: H7 (VTEC) serotype. The incubation period of the disease varies between 1 and 9 days, averaging 3-5 days. Clinical manifestations are extremely varied ranging from non-specific diarrhea, dysentery form of enteritis (with an invasion of the colon), choleriform enteritis (with the invasion of the jejunum-ileum mucosa) to hemorrhagic colitis and consecutively the hemolytic uremic syndrome (HUS). The hemolytic uremic syndrome is characterized by acute renal failure, thrombocytopenia and angiopathic hemolytic anemia. The most common form of HUS is associated with diarrhea and has the highest incidence in children, being the major cause of acute renal failure in children [9, 10]. The factor responsible in HUS manifestations occurred after the VTEC infection and the Shiga dysentery is a protein enterotoxin called the Shiga toxin or VTI. Initially, the hemolytic uremic syndrome mortality rate reached to 50%, but the evolution of medicine and modern treatment techniques have reduced the mortality rate to 3-5%, indicating that approximately 30% of the healed patients remain with long-term sequelae, such as acute kidney failure [8]. Escherichia coli is the cause in 80% (ExPEC pathotype) of ITU (urethral cystitis, cystitis, nephritis, pyelonephritis, etc.). Contamination may be downward (blood-borne) or upward, this route being the most common. Infection is favored by the existence of obstructive congenital lesions, post gonococcal infection strictures, urinary stasis via decubitus or pregnancy. Once the bladder mucosa is invaded, subsequently occurs the upward progression to the kidney and the infection stabilizes at this level as a result of slow mobilization of the phagocytes [11].

Lab diagnosis

The diagnosis of the Escherichia coli infection is made by addressing two strategies namely, identifying and highlighting the etiological agent of the VTI toxin. The usual method used by most diagnostic laboratories is the selective isolation of the etiologic agent (Escherichia coli O157H7; O157H), on the MacConkey with sorbitol culture media from stool [12]. The method's principle is that the strains of Escherichia coli O157: H7 do not ferment sorbitol in 24 hours and the colonies appear colored on the culture, characteristic that differentiates them from the other strains of Escherichia coli. If the isolated strains are suspected as belonging to the serotype O157, but ferment the sorbitol in 24 hours, then will be used the specific antisera for titration and the agglutination tests [13]. The detection of the VTI toxin can be achieved through the cytotoxicity method, cultivation of isolated strains from feces on Vero or HeLa cell lines. The genetic methods (PCR) are based on the detection of specific sequences of polynucleotides that encode the synthesis of VTI. A new and very precise method is MALDI TOF, namely the proteomics analysis through

mass spectrometry of the specific proteins extracted from the ribosomes [14]. The principle of the method consists in measuring the mass of the weights of the polypeptides from the sample to be examined, generating and comparing its spectrum with the spectrum from the data base of the mass spectrometer (figure 3).

Figure 3: Maldi TOF operating flow (after Bruker Daltonix)



Whole bacteria MALDI-TOF MS analysis
Laser
Data pre-processing
Multivariate analysis
Identification of bacteria independently by experimental growth conditions

Other lab diagnostic techniques that are being used are the ELISA, for the detection of the O 157 antigen from feces and the serological methods which, however, are of limited value because Escherichia coli does not always develop serum antibodies against the VTI toxin. Also, the LPS antigen used may develop cross-reactions with other biological agents, such as Brucella abortus.

Treatment and Prevention

The treatment of the infection with Escherichia coli O157:H7 is often symptomatic and consists in the treatment of the complications arising due to massive fluid loss, and consequently of the acute diarrhea condition. As a result of dehydration and permeabilization of the blood vessels, pathological changes take place in the kidney function with renal impairment and severe anemia, that may become complicated with hemolytic uremic syndrome (HUS), as apparently is the case in the current outbreak in Romania, since winter-spring 2016. The therapeutic management must take into account the avoidance of the abuse of antibiotics that can foster the development of strains of Escherichia coli, avoiding the administration of antispasmodic drugs with effect in slowing bowel, thus maintaining more toxins in the digestive tract and amplifying its harmful effects. It recommended avoiding administering products based on salicylates and ibuprofen that can increase digestive bleeding. The symptomatic treatment must include hydrodynamics and electrolyte rebalancing, blood transfusions and, if in severe forms of renal failure, dialysis. Prevention of disease is achieved by non-specific measures such as: washing hands with soap and water before and after eating; processing animal products and by-products; washing fruits and vegetables before consumption or industrial processing; avoid the consumption of raw animal products (milk) or semi-raw (hamburger); avoid the consumption of water from bacteriologically unverified sources; washing utensils that came in contact with meat or raw meat products; avoiding the use of unpasteurized juices, in particular for children, etc. In serious cases, potentially fatal, especially in young children, may be needed the treatment from the Intensive Care with perfusions, resuscitation and even peritoneal dialysis.

CONCLUSIONS

- Escherichia coli is from the Enterobacteriaceae species present in the colonic microflora of a healthy human, which has the largest epidemiological impact.
- The transmission mechanism of the infection is

"fecal-oral" as a result of the consumption of contaminated food or water, or by "dirty hands".

• The disease has been reported worldwide, being described numerous episodes of infection with Escherichia coli that caused multiple illnesses and sometimes even deaths (Walkerton Ontario/Canada, GHUSEC - Germany).

• Escherichia coli has three types of antigens: antigen "O" (somatic) antigen "H" (flagella) and antigen "K" (capsular) that can be highlighted by serologic antigen-antibody reactions. Combining all these antigenic variants theoretically result in 1,000 antigenic types of Escherichia coli.

• There are six known pathotypes of Escherichia coli involved in the EPEC diarrheal syndrome (intestinal pathotypes) and one pathotype involved in extraintestinal infections (urinary tract infections, meningitis, septicemia), ExPEC.

• Toxins are the most important category of virulence factors in Escherichia coli (heat-labile and heat-stable enterotoxin produced by ETEC strains, verotoxins 1 and 2 synthesized by VTEC strains, enteroaggregative heat-stable enetrotoxin of EAEC strains etc.).

• Clinical manifestations are extremely varied ranging from non-specific diarrhea, dysentery form of enteritis (with an invasion of the colon), choleriform enteritis (with the invasion of the jejunum-ileum mucosa) to hemorrhagic colitis and consecutively the hemolytic uremic syndrome (HUS).

• The Escherichia coli infection diagnosis is made by identifying the etiologic agent (biochemical tests, agglutination reactions, PCR, mass spectrometry) and by highlighting the VTI toxin (cell culture cytotoxicity assay, immuno-chromatographic methods, ELISA).

• The treatment is symptomatic and includes hydrodynamics and electrolyte rebalancing, blood transfusions and, if in severe forms of renal failure, dialysis.

• The prevention of infections with Escherichia coli is achieved by non-specific measures such as: washing hands with soap and water before and after eating; processing animal products and by-products; washing fruits and vegetables before consumption or industrial processing; avoid the consumption of raw animal products (milk) or semi-raw (hamburger); avoid the consumption of water from bacteriologically unverified sources.

Intellectual mobility in medical higher education system

Iulia Alecu[1], Horia Mocanu[2], Ioan E. Călin[1]

Abstract: *Intellectual mobility brings change, there is the primary factor in the way of progress and optimal premise of human being development from theoretic and practice regards. Medical Higher Education, worldwide, is generally similar in structure and consistency, but different in typology of presentation, teaching, learning and assessment. In fact, general medicine, as a subject refers to the same biological body, but presented differently depending on culture, space and under various methods of teaching and learning.*

The idiom of intellectual mobility is not new, but according to globalization, which we live at the present times, brought the mobility in the main plan of Europeanization, a new plan, with continues sustainable development and maybe of success. By institutional mobility, both for students and for academic staff, an exchange means a period of one academic year or a semester, for students and, for two days to several months for academic staff, into a foreign university. These stages of study, practice, and teaching take place most frequently within the Erasmus + framework, have been of 30 years in Europe and 20 years in Romania. Also, there are other programs that can perform intellectual mobility, but the most well-known is Erasmus program, where European Commission has allocated the biggest legal and financial budget framework. Overall activity program features has a variety of tools to be deployed and an inter-institutional framework with qualified staff to manage it.

Keywords: *medical education, recognition, higher education, mobility, Erasmus program*

INTRODUCTION

General Medicine as an important branch of study has a special status in the conduct of mobility as importance of the field and also under emotional aspect.

Intellectual mobility takes a certain mental patterns generated by education and a native predisposition, regardless of the field. Along with this added dynamic appeal cases handled by the abstract representations. In the field of medicine is worked with a high degree of abstraction. Or spatial relocation and mobility means mental derived including concrete way of their operationalizing in the two phases of the medical profession: correct diagnosis and treatment of the patient, not the disease. Appeal to intellectual mobility, is done often in the holistic approach to the patient. The doctor represents, on the one hand a mechanic and on the other hand a sociologist. This would be the condition of being a successful doctor. There is also the assumption that both treatment and technique coordinate the doctor to a successful performing.

Casuistry with high risk requires determination,

[1] Wallachia University

[2] Titu Maiorescu University, Bucharest

curiosity and professional beliefs. However, it is based on a dominant personality characteristic correlated with a predominantly emotional intelligence, and then on IQ. But there is a less explored area of the mind of a physician or a future doctor, a student, how to manage frustration generated by failure in high-risk cases, but not only. Failure, in any other domain generates lessons learned that are grouped in a simple taxonomy:

1. Lessons indicating approaches “know how";
2. Lessons to refute or confirm hypotheses absolutely absurd;
3. Lessons to optimize cases generally valid but wrong managed.

Thus, intellectual mobility in general, depends of subjective perception of reality itself the objective of playfulness and cognitive operators with which man is accustomed routinely to operational abstractions. Medical education has the same topology and provides almost the same bibliographic regarding symptoms of the disease; unfortunately get to treat the disease using methods quite invasive.

Such patterns of study are known in medical education through student mobility from one education system to another. Exchange of experience, for a period from one university to another can bring new knowledge, new methods of learning, but also a personal self, psycho-emotional development.

Erasmus mobility can bring competitive doctors on the labor market and ensure a quality structure, but the real problem is the distribution on the labor market.

As it is well known Romanian doctors prefer to work in European hospitals or beyond Europe, which is not bad, on the one hand, but on the other hand it led to a destabilization of the health system in Romania. So Erasmus mobility tended by a medical mass migration.

Naturally, in this context a basis is economically and socially disadvantaged in Romanian hospitals and moral degradation of the system.

MEDICAL HIGHER EDUCATION IN DRESDEN, ROME AND BUCHAREST

A brief history

A brief history of medicine proves that it was practiced of ancient times from trained professional. History and times prove how the society have changed and it is also in a continuous changes in the approach to sickness and disorder from ancient beginnings

It is well known in the world that medical services were provided for the poor people in monastic hospitals. The care was rudimentary way and rather palliative. As we can observe also medical services and school education, in any domains started from the monastic area, in churches. As just a thin remembering it can be named that culture and civilization started around the human necessity of norms and rules issued by the spirituality.

In the 9th century there were some medical schools in Italy. The influence from other nations as: Greek, Latin, Arabic and Hebrew gave an international dimension. Students learn three years as preliminary courses and five years of medical schools. Nowadays they study five, six or seven years in Europe and in SUA more than ten years.

Italy is the place where medical universities were founded, after came France and England which developed medical schools. So we can see from the beginning the health science started in an internationally manner and mobility and migration are quit ancient and were very important in the development of it.

Today according to the progress of technology, techniques and information system mobility is very used and normal in the society.

Recognition of studies

In order to define studies in Erasmus Program we have to analyze its framework. The main problem is the recognition in making Erasmus.

Although there is a desired of full recognition of Erasmus studies, according to the Erasmus Charter, it is not possible, discussing the case by case,

depending on the curriculum and structure. Of course, that is an ideal situation that a degree program can be accepted fully recognized, but there are features that can be dealt with individually. Although Erasmus Charter directs the full recognition and, in general, universities are trying to respect this principle, even though at the end of the program, there are people involved in Agencies of Recognition and Accreditation of Studies from all over Europe, not easily accept that Erasmus has a special pattern, easily convertible by ECTS and also has all instruments and forms provided. We will see a simple case which presents two distinct situations of curricula on a few subjects of study. We'll see how a curriculum in three different states differ and how to work through the transformation to studies from a curriculum to another, by grades, ECTS obtained both from practical or clinical training and courses. Quantification of studies must be easy and in interest of students. Of course it is of great important qualitative component, especially in the field of medicine. But always should take into account the socio-cultural characteristics, adjusting the student in a new cultural space and psycholinguistics barrier.

In the context of Europeanization and for exemplifying the above situation exposes three major universities with medical schools, in Europe.

Universitatsklinikum "Carl Gustav Carus" Dresden Technische Universität of Germany, especially the ENT discipline; Universita Degli Studi di Sapienza, Rome, Italy, with examples on general surgery and internal medicine and Titu Maiorescu University in Bucharest, Romania, as a university of origin/home university, which makes recognition and equivalence studies.

Germany is a country of art, technique and study continuously, so the team from ENT created a standardized teaching maneuvers examination by a small guide, so that students can observe organized clinical examination of Otolaryngology. Consideration is made all the standardized by checking maneuvers in a form, for a period of 6 minutes of examining a patient. This calculates a score of the exam, and the form can be filled by two examiners for the compared results.

Such an experience has brought by an academic staff that has benefited of teaching stage in Dresden. Today, the ENT method was implemented in Bucharest for teaching and assessment the subject. One such example is enlightening to harmonize the methods of teaching and assessment, job shadowing lead to the development of new skills.

Regarding the Recognition of Studies facts are the discussions become slightly rigid and austere although the program is provided with all the necessary tools.

A student who chose as subjects of study maxillofacial surgeon, a course of a single module named Head has 1 ECTS, but the workload is the same as that of a course of otolaryngology at Bucharest, which has 4 ECTS. Also, the grading system is different. In Germany the scale grades are from 1 to 5, and in Italy from 18 to 30; 1 ECTS has 25 hours of workload. In Romania, at faculty of medicine 1 ECTS has approximately 14 hours of workload. Depending on the workload is denoted by ECTS, 30 for a semester and 60 per academic year, which should be equivalent between higher education systems, but they are not. Module Thorax includes the following disciplines: Cardiology, Angiology, Pulmonology, Vascular Surgery, Thoracic and Cardiac has a volume of 10 ECTS, if studied together, if it divides, then the number of ECTS is divided too, in Romania they are separate disciplines. In Italy, Internal Medicine and General Surgery is a module that measures 12 ECTS together, and in Romania internal Medicine has 6 ECTS for the first semester and for the second semester it has 5 ECTS, in the end there are 11 ECTS, just Internal Medicine. General Surgery is another subject and it has 4 ECTS for the first semester and 4 ECTS for the second semester; they are totally different from one system to other. Such recognition is based on workload and always is made in the favour of the student, or should be.

In Germany the focus is on clinical stages, more than in Italy. In Romania, specialized practice/training is done since of the first year of study, according to the students' testimony.

Although there are differences in the three systems

of teaching and learning, Erasmus has provided the tools; study contract/Learning Agreement, and students can choose their subjects to be studied and disciplines which will be equate to return. Studies are, or should be recognized, integrum, full recognition under the Erasmus Charter. If the student does not fulfill the learning agreement he/she will support additional exams from local education until completion of ECTS number needed to pass the academic year. These are predetermined patterns of procedure and related methods for classification and institutionalization of each institution. What becomes interesting is the prospect of personal development of each individual differs from person to another depending on operators and cognitive education.

There are three factors that can prevent full recognition, as following:

1. Changing subjects of study during mobility, Erasmus Learning Agreement provides that rule can be changed, only in the first 14 days of mobility. Thus, changing the curriculum content, can prevented full recognition procedure because of the time period from the moment of making the new choice of new disciplines and to the approval by the academic tutor from home institution.

2. A second factor that keeps the procedure and otherwise representing a procedural error is soliciting approvals for the recognition and equivalence studies to the professors who are tutor of the disciplines. Thus, the holder of course, may be not sufficiently informed and decide in the detriment of the student. Erasmus Rule requires the application of Charter based on acceptance of Erasmus in function. So is forbidden that a tutor can decide regarding his/her discipline.

3. Finally a third factor, which prevents full recognition, is negative influence of the party who decide subjective and would not assumes the recognition of Learning Agreement. These are isolated cases, and in recent years almost no longer exist. The procedure for recognition and equivalence is the essential characteristic of students in the decision to go in Erasmus mobility.

According to the magazine Prime 2010, only 19% of students surveyed are convinced that it will not benefit from an exchange. The rest of the students who responded to the questionnaire in the same magazine argued that regardless of the recognition of studies, mobility itself and experience are more important than the recognition of studies, thus they assuming full academic exchange activities. Of course that always the activity must be tried separately according to each case. If the student wishes on its own initiative to have examinations in the subjects of home university, it is not prevented, or if the student did not follow important disciplines for future examinations of competence, then it will have them at the return from the mobility without charge of any fee.

There is also a risk that the student take courses that are done in the near future/years of study in the home university and through full recognition, the student would be forced to repeat subject mobility in the coming years. As such, the choice of subjects, from a curriculum structured around six years can be challenging even for academic tutor. This happens because the curricula are not similar, nor how to be similar. Bologna process does not seek to standardize the Higher Education, but seek to a better harmonization of curricula, a socio-cultural and economic uniformity.

If the student is studying disciplines in the curriculum of the home university is doing in a upper year, the University, study case of this research, recognizes full program of study at the partner university and mention the time spent abroad in the Diploma Supplement, and recognizes discipline by discipline in the years that match the local program, and to promote appropriate student take exams in the subjects of study sessions legal up, and in special cases can be organized special sessions for Erasmus students. Whatever, the situation of recognition and equivalence of studies is made, only in students' favor without affect the merit place at home university.

Despite these shortcomings of procedures for recognition of studies, students wishing to repeat the experience to the extent permitted by the Erasmus program.

Most often students after followed a study program they would like to follow a clinical internship. From the experience of the university concerned, they apply after completing their studies in residency programs in the world. University receives per few times a year, forms requesting certification of studies by agencies of recognition of medical studies in the USA and Canada.

Table 1: Example of a model of recognition studies, in Germany
(it can be observed that the students pass more than 5 ECTS at home university)

Name of the subject	ECTS	Grade in Germany	Grade in Romania
Maxillofacial Surgery	1	1,5	10
Cardiology, Angiology, Pulmonology, Vascular Surgery, Thoracic and Cardiac	10	2	9
Dermatology & Venereology	3	4	5
Rheumatology	2	attended	
Pathophysiology & Medical Biochemistry and Laboratory Diagnostics	9	4	5

It is mention were equated the subjects studied in Germany in the V th year, semester 1 of the study, under the Erasmus Charter, after the student has pass the remaining number of 5 ECTS, as follows:

Name of the subject	ECTS	Grade in Romania
Pneumology	4	7
Occupational diseases	5	8
Radiology	5	9
Gerontology		10
TOTAL	14	

Analyzing the situation of a student who was Erasmus, in the fifth year of study at the University of Dresden, after she came back home observed willingness to continue the study and mobility training, such as she obtained a period of 2 months in a hospital in Germany, combining theoretical and practical work with a clinical internship. Besides the recognition and equivalence of procedural, student mobility has made a qualitative leap in medical education, as well as psycholinguistic improving linguistic competence and went beyond customary in the sphere of national education.

CONCLUSION

Mobility in medical education can make steady progress in what is called globalization, harmonization of curricula and skills in the labor market. The main objective of globalization and mobility function is preventing and overcome poverty and habits that can hinder knowledge and human progress. The internationalization of education is a process of development and a better preparation of students for a globalized society, based on knowledge and skills. Higher education institutions have the main role to prepare graduates for the labor market in the line with international policies of globalization. Mobility brings extra value to Europe and is a sine qua non of human development in relation to the labor market, the practical problem that remains in the knowledge era is the economic and political, social and moral worldwide crisis, otherwise unmanageable. Now it is felt the effects of the global turmoil, but concrete results are likely to be known around 2050.

The influence of homocysteine on osteoporosis

Elena Rusu[1]

Abstract: *Osteoporosis is a major health problem, and the economic costs are expected to rise due to an increase in life expectancy throughout the world. Its major consequence is fractures, and especially hip fractures are associated with institutionalization and increased mortality. Homocysteine is an amino acid intermediate formed during the metabolism of methionine. Homocysteinuria is a rare autosomal recessive biochemical abnormality which causes elevated plasma concentrations of homocysteine and severe occlusive vascular disease. In patients with homocysteinuria, there is an increased prevalence of skeletal deformities, including osteoporosis, which is a primary risk factor for hip fracture. The high prevalence of osteoporosis among patients with homocysteinuria suggests that high levels of plasmatic homocysteine may also increase the risk of fractures. Nutritional factors such as vitamins B12, B6, and folate are cofactors in homocysteine metabolism, and vitamin intakes may inversely affect plasma homocysteine levels.*

Keywords: *osteoporosis, homocysteine, hip fracture*

INTRODUCTION

Osteoporosis is a major health problem, and the economic burden is expected to rise due to an increase in life expectancy throughout the world. Its major consequence is fractures, and especially hip fractures are associated with institutionalization and increased mortality. The prevalence of osteoporosis increases with age due to an imbalance in the rate at which bone is removed and replaced during the bone remodeling cycle, which is an important physiological process that is essential for maintenance of a healthy skeleton.

Pharmacological interventions may prevent 30-60% of fractures in patients with osteoporosis. Common sites for osteoporotic fracture are the spine, hip, distal forearm and proximal humerus. The remaining lifetime probability in women at the menopause of a fracture at any one of these sites exceeds that of breast cancer (approximately 12%), and the likelihood of a fracture at any of these sites is 40% or more in developed countries [1].

The level of bone mass can be assessed with adequate precision by measuring bone mineral density using dual X-ray absorptiometry. It has

---

[1] Titu Maiorescu University, Bucharest

been suggested that bone strength may be reflected, independently of bone mineral density level, by ultrasonic measurements of bone and by measuring bone turnover using specific serum and urinary markers of bone formation and resorption.

Physical activity as a way to prevent osteoporosis is based on evidence that it can regulate bone maintenance and stimulate bone formation including the accumulation of mineral, in addition to strengthening muscles, improving balance, and thus reducing the overall risk of falls and fractures. It is well known the important influence of hormones as well as dietary and specific nutrient abundance on bone, growth and health is emphasized and premature bone loss associated with dietary restriction and estradiol withdrawal in exercise-induced amenorrhoea [2].

OSTEOPOROSIS

It is becoming increasingly clear that there is a relationship between growth and development in early childhood and bone health in old age. In fact, suboptimal bone development leads to a reduction in peak bone mass, and a higher risk of osteoporotic fracture later in life. Osteoporosis is a skeletal disorder characterized by low bone mass and micro-architectural deterioration of bone tissue, with a consequent increase in bone fragility. Preventative strategies against osteoporosis can be aimed at either optimizing the peak bone mass obtained, or reducing the rate of bone loss.

One of the largest risk factors for fractures is a reduction in bone mineral density. Risk factors for fracture can be purely skeletal-related affecting bone mass, bone geometry, bone micro-architecture and bone turnover, or solely fall-related such as neuromuscular dysfunction, poor balance, cognitive impairment, cardiovascular instability, reduced visual acuity and sedative medications. Others risks are both skeletal and fall related such as age, genotype, and family history of fracture, weight, weight change and mobility [3]. Falls history is a further independent risk factor for fracture, in particular in men [4]. About 50% of white women and 20% of men will have an osteoporosis-related fracture in their lifetimes. Fractures of the hip and spine may be disabling and are associated with mortality rates that are about 20% greater than that of an age-matched population. The goal of any treatment for osteoporosis is to improve bone strength, thereby decreasing fracture risk.

Bone remodeling is the result of two opposite activities, the production of new bone matrix by osteoblasts and the destruction of old bone by osteoclasts. The rates of bone production and destruction can be evaluated either by measuring predominantly osteoblastic or osteoclastic enzyme activities or by assaying bone matrix components released in the bloodstream and excreted in the urine [5].

Factors which influence negatively the osteogenetic potential are age, nutrition diseases and endocrinopathy, ionized radiations treatments and different toxic factors. It has been scientifically proved the fact that elder patients have decreased general biological potential. Regarding the bone system, there occur structural changes which weaken the resistance, to which we can add a diminishing of the response potential towards harmful factors. These lacks are considered to belong to multiple causes: a diminishing of the vitamin D action and of calcitonin, hyperactivity of the parathyroid hormones with osteoblast inhibition, etc. [6] As a result, osteolysis-osteo-synthesis dynamics is reversed, resorbing processes become dominant: osteodystrophy, osteoporosis, senile osteopenia, metabolic and endocrine osteopathy, which, affecting the very bone structure, are the main causes of diminish in the osteogenic potential in elderly patients. Nutrition diseases and endocrinopathies seem to have the most harmful effects on osteogenesis and the repairing processes of the bone tissue.

The evaluation of biochemical markers of bone turnover has been useful in clinical research. However, the predictive factor of these

measurements is not defined clearly, and these findings should not be used as a replacement for bone density testing [7]. There is a high prevalence of calcium, protein and vitamin D insufficiency in the elderly. Calcium and vitamin D supplements decrease secondary hyperparathyroi-dism and reduce the risk of proximal femur fracture, particularly in the elderly living in nursing homes. Sufficient protein intakes are necessary to maintain the function of the musculoskeletal system, but they also decrease the complications that occur after an osteoporotic fracture.

HOMOCYSTEINE

Sulfur is the seventh most abundant element measurable in the human body and is supplied mainly by the intake of methionine, an indispensable amino acid found in plant and animal proteins. Inhibition of cystathionine-β-synthase activity causes the upstream sequestration of homocysteine and the downstream drop in cysteine and glutathione [8]. Homocysteine is an aminoacid which contains a thiol group formed by methionine intracellular demethylation (alpha amino gama methylthio butyric). In plasma, homocysteine is found free in oxidized or disulphidic form, linked to proteins. Homocysteine has two ways to be metabolised, a metabolic path is represented by transsulfuration to cysteine through cystatin synthetasis, enzymes which need vitamin B6 as co-factor (proving the need of vitamin B6 administration during the treatment). Synthesis of cysteine as a product of the transsulfuration pathway can be viewed as part of methionine or homocysteine degradation, with cysteine being the vehicle for sulfur conversion to end products (sulfate, taurine) that can be excreted in the urine. Transsulfuration of homocysteine to cysteine is catalyzed by two pyridoxal 5′-phosphate-dependent enzymes, cystathionine β-synthase and cystathionine γ-lyase. The transsulfuration pathway is responsible for catabolism of the carbon chain of methionine, release of the amino nitrogen in a form that can be funneled into pathways of nitrogen excretion, and transfer of Met sulfur to serine to synthesize cysteine [9].

Another metabolic path is remethylation to methionine in the presence of methylentetra-hydrofolate reductase (MTHFR) and methionine synthesis in the presence of folic acid as an under layer for vitamin B12 as co-enzyme (proving the need of folic acid and vitamin B12 administration during the treatment). There are studies which proved that the level of homocysteine in blood is inversely proportional with folate levels, vitamin B12, vitamin B6 and oxygen intake induced by these vitamins [10].

Homocysteinuria is a rare autosomal recessive biochemical abnormality which causes elevated plasma concentrations of homocysteine and severe occlusive vascular disease. In patients with homocysteinuria, there is an increased prevalence of skeletal deformities, including osteoporosis, which is a primary risk factor for hip fracture. Blood levels of total homocysteine increase throughout life in men and women. Prior to puberty, both sexes enjoy optimally healthy levels (6 µmol/L). During puberty, levels rise, more in males than women, reaching, on average, almost 10 µmol/L in men and more than 8 µmol/L in women. As we age, mean values of homocysteine continue to rise and the concentrations usually remain lower in women than in men. Adults without homocysteinuria who have high homocysteine levels are also at risk for fractures. Thus, elevated plasma homocysteine concentrations (>14 µmol/L) are associated with osteoporosis and may increase the risk of hip fracture, in both men and women. These can lead to substantial disability, high medical costs, and death [11]. Elevated plasma homocysteine concentrations are associated with reduced physical performance and muscle strength in older women [12].

Hyperhomocysteinemia may contribute to the development of osteoporosis. High hyper-homocysteine and low vitamin B12 concentrations were significantly associated with low bone turnover markers, high markers of bone turnover, and increased fracture risk [13]. Folate and vitamins B12 and B6 are major determinants of homocysteine concentrations in older persons [14]. The B vitamins folate, B12, and B6 are important cofactors in homocysteine metabolism, and low status of these

nutrients is the primary determinant of elevated plasma homocysteine concentrations in elders. Patients with pernicious anemia have decreased bone mineral density at the lumbar spine, and in comparison with the general population they have almost double the risk of hip fracture. Gene polymorphisms related to homocysteine metabolism also may result in high homocysteine levels. Thus, nutritional factors such as B12/folate deficiency and genetic factors may affect homocysteine levels and contribute to fracture risk.

Hyperhomocysteinemia is regarded as a risk factor for ischemic stroke and for hip fractures in Parkinson's disease patients receiving levodopa [15]. The high prevalence of osteoporosis among patients with homocysteinuria suggests that hyperhomocysteine may also increase the risk of fractures [16]. Higher plasma levels of total homocysteine and folate were independent predictors of coronary heart disease [17]. In the Framingham study authors had shown that plasma total homocysteine concentration is inversely related to the intake and plasma levels of folate and vitamin B6 as well as vitamin B12 plasma levels. Almost two-thirds of the prevalence of high homocysteine is attributable to low vitamin status or intake. Elevated homocysteine concentrations in plasma are a risk factor for prevalence of extracranial carotid artery stenosis of at least 25% in both men and women [18]. Some researchers want to determine if there is a possibility that plasma total homocysteine may serve as an indicator of the status and perhaps the intake of a number of vitamins, including folic acid, vitamin B12, and vitamin B6. This possibility derived from the large number of studies that implied that methionine metabolism is tightly regulated and from other studies that showed that deficiencies in the above vitamins are often associated with hyper-homocysteinemia.

It was shown that premenopausal women have lower homocysteine levels than men and postmenopausal women. Higher plasma levels of total homocysteine concentrations in men than in women may be explained by differences in muscle mass, hormone and vitamin status [19]. Factors that influence total homocysteine plasma levels in the general population include diet, in particular folate intake, blood levels of folate, vitamin B12, and betaine, renal function, and the MTHFR 677C>T polymorphism [20]. There are studies to establish that increasing evidence that plasma total homocysteine is inversely associated with bone health. It has been speculated that moderately elevated total homocysteine levels could contribute to osteoporotic changes, based on the fact that osteoporosis is a common phenomenon in homocysteinuria. High total homocysteine and low vitamin B12 concentrations are significantly associated with high levels of markers of bone turnover, and relations have been reported between total homocysteine and markers of bone resorption [13].

Elevated plasma total homocysteine, deficiencies of folate and vitamin B12 are associated with risk of osteoporosis and fracture. In some studies, there were examined whether plasma levels of elevated plasma total homocysteine, folate, and vitamin B12 predicted hip fracture [21]. They found that elevated plasma total homocysteine is a predictor for hip fracture among elderly men and women.

CONCLUSION

In patients with homocysteinuria, there is an increased prevalence of skeletal deformities, including osteoporosis, which is a primary risk factor for hip fracture. The high prevalence of osteoporosis among patients with homocysteinuria suggests that hyperhomocysteine may also increase the risk of fractures. Nutritional factors such as vitamins B12, B6, and folate are cofactors in homocysteine metabolism, and vitamin intakes may inversely affect plasma homocysteine levels.

REVIEW ARTICLE

Article received on August 25, 2016 and accepted for publishing on December 15, 2016.

Clinical features of oral angiolipoma – A review

Shishir Ram Shetty[1], Sura Ali Ahmed Foud Al- Bayati[1], Shakeel Santerbennur Khazi[1], Sesha Reddy Manchala[1]

Abstract: *The aim of this paper was to analyze the data obtained from case reports of oral angiolipoma in terms of age and gender distribution, site of occurrence, nature (intraosseous/ extraosseus) and infiltration. an internet search using Google scholar and Pubmed engine was carried out using search terms 'angiolipoma' and 'oral'/'mouth'. English literature full text articles and abstracts of oral angiolipoma obtained from 1976-2016 were analyzed for clinical data and presented in this article.*

Keywords: *angiolipoma, oral, mouth*

INTRODUCTION

Angiolipoma (AL) is rare variant of lipoma which consists of both fatty and vascular elements. [1] ALs were first describe by Bowen in the year 1912. [2] The first published report of an oral angiolipoma was by Davis et al in 1976. [3] Angiolipomas account for 5 to 17% of all the lipomas occurring in the oral cavity, lipomas themselves account for 1-5% of all oral benign tumors [1]. Since oral angiolipoma is rare benign tumor, published reports are mainly restricted to case reports. [4,5]

CLASSIFICATION OF ANGIOLIPOMAS

Based on their studies Gonzalez-Crussi et al. classified angiolipomas into infiltrating and non-infiltrating. angiolipomas.[6] The non-infiltrating angiolipomas are encapsulated, whereas infiltrating angiolipomas lack this capsule.[6] Among the two, infiltrating angiolipoma (IAL) is a rare lesion typically characterized by infiltration of the surrounding structures, especially skeletal muscle.[7] Based on whether the angiolipoma occur in bone or soft tissues they can be classified as intra-osseous or extra-osseous types.[8] The intra-osseous variety is extremely rare in comparison to the extraosseus variety. [8,9]

METHODOLOGY FOR ANALYSIS OF THE CASE REPORTS

An analysis of the data obtained from case reports of oral angiolipoma in terms of age and gender distribution, site of occurrence, nature (intraosseous/ extraosseus) and infiltration. An internet search using Google scholar and pubmed engine was carried out using search terms 'angiolipoma' and 'oral'/'mouth'. Full text and abstracts of oral angiolipoma cases obtained from 1976-2016 were analyzed. (Table 1)

GENDER PREDICTION OF ORAL ANGIOLIPOMA

Fregnani ER et al (2003) stated that male to female

---

[1] College of Dentistry, Gulf Medical University, Ajman, United Arab Emirates

ratio from these intraoral angiolipomas was 1.4:1, in contrast to cutaneous angiolipomas and intraoral lipomas as a group, which either shows no sex predilection or a slight female predilection.[10]

Table 1: Clinical data obtained from full texts and abstract of oral angiolipoma case reports published from the year 1976-2016

Researcher	Year of publication	Type infiltrating/ non-infiltrating	Gender	Age group	Site	Extraosseous/ intraosseous
Davis et al [3]	1976	-	-	-	hard palate	
Polte HW et al [30]	1976	-	-	-	mandible	intraosseous
Weitzner et al [35]	1978	-	male	4-year-old	cheek	
Campos et al [34]	1980	-	-	-	cheek	
Lewis DM et al [31]	1980	-	-	-	mandible	intraosseous
Brahney CP et al [21]	1981	-	-	-	tongue	
Flaggert et al [19]	1986	-	female	8-year-old	palate	
Reilly et al [15]	1988	-	female	infant	parotid	
Lin SC et al [17]	1989	-	male	49-year-old	tongue	
Manganaro AM et al [32]	1994	-	-	-	mandible	intraosseus
Ali MH et al [36]	1996	-	-	-	cheek	
Sugiura J et al [16]	1999	infiltrating	-	-	muco-buccal fold	
Ida-Yonemochi H et al [12]	2005		male	69-year-old	buccal mucosa	
Altug HA et al [11]	2009	non-infiltrating	male	22-year-old	cheek	
Gerard N et al [20]	2009	-	-	-	upper lip	
Thakur B eta al [37]	2010	non-infiltrating	female		cheek	
Palaia G et al [38]	2011	non-infiltrating	female	66-year-old	cheek	
Yanase S et al [13]	2011	non infiltrating	male	76-year-old	cheek	
Sah K et al [4]	2012	non infiltrating	female	9-year-old	upper lip	
Hemavathy S et al [9]	2012	-	female	21-year-old	mandible	intraosseus
Silva-Junior GO et al [5] 2 cases	2013	non-infiltrating	male	57-year-old	cheek	
	2013	non-infiltrating	female	29-year-old	masseteric region	
Shahi AK et al[14]	2014	infiltrating	female	9-month-old	cheek	
Mohiuddin SA et al [39]	2014	non-infiltrating	male	46 year old	mandibular buccal vestibule	
Ohnishi Y et al [7]	2015	infiltrating	female	74 year old	lower lip	
Chandrasekaran D et al [1]	2016	non infiltrating	female	55-year-old	palate	

However most of the other researchers have stated that no gender predilection. [1,7,11,12] According to the data obtained from the analysis of the reports, seven cases were in males, ten cases occurred in females. However we could not obtain enough data regarding gender in 9 case reports.

AGE PREDILECTION OF ORAL ANGIOLIPOMA

Fregnani ER et al (2003) stated that the mean age of the affected patients was 37 years (range, 4 to 81 years),which was in contrast to other variants of lipomas occurring in the oral cavity that occur in the 50-60 year age group.[10] On analysis of the available case reports we found that occurrence of oral angiolipoma ranged from a 4-month-old to 76-year-old individual.[13,14,15] Infiltrating angiolipomas are usually diagnosed in older individuals.[7, 16, 17, 18]

SITE PREDILECTION OF ORAL ANGIOLIPOMA

Angiolipoma have a prediction of occurrence in the

buccal mucosa, followed by lip.[5] Occurrence in palate has been reported in few cases.[1,3,19]. Upper lip involvement is more common than lower lip.[4, 20] Few cases have also been reported in tongue.[17, 21] However many of the cases of angilipoma of tongue have the muscle component along with fat and vasculature and thus are termed as angiomyolipoma.[22,23, 24, 25]. The occurrence of angiolipoma in the parotid has also been reported.[15] The benign angilipomas occurring the salivary gland have glandular component apart from adipose and vascular components and are called as sialoangiolipoma.[26] Such cases have been reported to have been observed in parotid and submandibular gland.[27, 28] A rare case of a lipoma with vascular and salivary gland components has been reported in palate also.[29]

INTRAOSSEOUS ANGIOLIPOMA

The first case of intraosseous angiolipoma was by Polte in the year 1976.[30] Mandible is the most common site of occurrence of intraosseous angiolipoma.[9,31,32] Intraosseous lipoma may present a range of clinical manifestations such as swelling, or presence of neurologic signs (hypesthesia or paresthesia) or can be totally asymptomatic.[9] On radiographic examination the lesion usually presents as well-circumscribed radiolucency.[9] Extraction related trauma is believed to be cause for intraosseous angiolipoma of the jaws. Fatty metamorphosis of a central hemangioma and possible variation osteoporotic bone marrow defect are other suspected etiologies. [33]

INFILTRATING ANGIOLIPOMA

Infiltrating angiolipomas lack encapsulation and are typically characterized by infiltration of the surrounding structures.[6,7,14,16] In contrast to the non-infiltrating angiolipomas are well encapsulated. [34,35,36,37,38]. Infiltrating angiolipoma usually occur in older individuals but a report of 9-month-old diagnosed with infiltrating angiolipoma has recently been published.[14] Infiltrating angiolipomas are also associated with symptoms muscular pain and neural deficits.[39,40]

CONCLUSION

In this review we have made an attempt to analyze the clinical features of oral angiolipoma in terms of its gender predilection, site predilection, infiltrative nature, intra/extraosseus types. The information obtained from this review could aid the clinicians in diagnosis this extremely rare benign lesion.

SYSTEMATIC REVIEW

Article received on January 18, 2017 and accepted for publishing on March 19 2017.

Hepatocellular carcinoma – A review

Gaudia V. Mănescu-Avram[1], Cătălina Diaconu[1], Laura Voicu[1], Mariana Jinga[1,2], Florentina Ioniță Radu[1,3], Daniel O. Costache[1], Raluca S. Costache[1,2]

Hepatocellular carcinoma is a major public health issue, occupying the fifth place of the most common cancers and the third leading cause of cancer in the world. The incidence of HCC has increased in the past decade thanks to higher rates of HCV infection and improvements in the management of cirrhotic patients. The regions with the highest incidence of HCC are, in descending order: Eastern Asia, sub-Saharan Africa, South-East Asia and southern Europe. It has been observed that etiological factors which lead to HCC have a heterogeneous distribution; thereby, in Asia and Africa the most common risk factor is HBV infection, increased by ingestion of aflatoxin B1-contaminated food that is associated with a specific mutation in the p53 tumor suppressor gene. HCC may develop earlier in these regions, most common in a noncirrhotic liver. In developed countries, the principal risk factors are HCV infection and alcohol-related cirrhosis [1].

RISK FACTORS

The main risk factors involved in the development of HCC are chronic viral infections, hemochromatosis and alcoholic cirrhosis. Other risk factors which may lead to HCC are cirrhosis secondary to autoimmune hepatitis and Wilson disease. In the last years, diabetes was suggested as HCC risk factor in numerous studies. However, it is difficult to study the possible association between the two concepts, because diabetes is a risk factor for nonalcoholic liver disease and nonalcoholic steatohepatitis , which may lead to the appearance of liver fibrosis, of cirrhosis, and finally to HCC, being known the fact that the principal risk factor is the presence of cirrhosis, no matter of the cause. On the other hand, end stage liver disease may herself determine glucose intolerance and diabetes. Studies show that >90% of patients with cirrhosis have glucose intolerance and 30% have diabetes [2].

Cirrhosis is a premalignant statement independent to the etiology. Liver cell dysplasia is probably the intermediate step. Patients with cirrhosis and high rates of cellular proliferation are at high risk to develop hepatocellular carcinoma.

HBV and HVC. It has been shown that there is an interval of 15-40 years between the development of chronic hepatitis and the appearance of hepatocellular carcinoma and the distance is shorter for the virus C infection. For hepatitis B, is important to know the age at which the infection occurred- patients infected in the prenatal period or in childhood are at high risk to develop chronic hepatitis or to become chronic carriers and at the same time to develop cirrhosis and hepatocellular carcinoma.

HBV is responsible for almost 80% of hepatocellular

[3] Titu Maiorescu University, Bucharest, Romania

carcinoma. Vaccination against HBV and antiviral treatment are the most efficient ways for prevention. HBV seems to be directly and indirectly carcinogenic. There is a connection between the level of replication of virus B (viral load) and the risk of hepatocellular carcinoma. HBV integrates into the genome host and the viral load precedes almost always the development of hepatocellular carcinoma, leading to mutations at the place of integration and high levels of TNF-α. HBx protein inhibit the p53 tumor suppressor gene and activate genes implied in the control of cellular growth. Patients with HB antigen positive infected with delta virus have a reduced incidence of hepatocellular carcinoma, probably because delta virus suppress HBV.

HCV, despite HBV, is an ARN virus which does not have reverse transcriptase and can't integrate into the genome host. The manner of carcinogenesis production is uncertain, but probably is generated by chronic hepatitis and cirrhosis. Persistent hepatitis with high levels of alanine aminotransferase is a semnificative predictor of hepatocellular carcinoma development. Accelerated cellular turnover is implied in the pathogenesis of cirrhosis; at the same time, it has been demonstrated that patients with persistent hepatic injury develops a sort of HCV species that metamorphoses in time, meanwhile patients with normal aminotransferase levels have a stabile infection with a single species of HCV. It seems that during this process are produced species more ,,oncogenic” of HCV core protein. HCV reacts with cellular genes that regulates the cellular growth and differentiation. P53 activity is suppressed and tumor suppressor functions are disabled. HCV core proteins are probably oncogenic [3].

Alcohol intake increases four time the risk of hepatocellular carcinoma development, especially in older patients; cirrhosis is always present. The risk of hepatocellular carcinoma is highest in patients with chronic hepatitis and persistent hepatocellular injury. Patients who stop the alcohol intake reduce considerably the risk of hepatocellular carcinoma development. The enzyme induction mediated by alcohol increases the conversion of co-carcinogens in carcinogens.

Aflatoxin B1, produced by Aspergillus flavus and Aspergillus parasiticus is a pro-carcinogen which is converted in the liver into a metabolite by the cytochrome P450 system at the 8,9-vinyl bond with the formation of an unstable reactive intermediate, aflatoxin B1-8,9-epoxide, which can bind covalently to DNA. The result is the formation of Aflatoxin B1-guanine adducts and protein- aflatoxin B1-albumin and other protein adducts. In addition, aflatoxin B1 acts as a carcinogen by mechanisms that include the formation of reactive oxygen species leading to increased hepatic damage [4].

Sex and genetic predisposition. Globally, hepatocellular carcinoma is 3 times more frequent in males than females. In regions with increased incidence, familial history of hepatocellular carcinoma is an important factor. It is possible to exist a genetic predisposition for hepatocellular carcinoma or a familial predisposition for an extended phase of HBV replication.

Other factors. Hepatocellular carcinoma is a rare complication of autoimmune hepatitis and primary biliary cirrhosis; it may occur frequently in hemochromatosis (in almost 45% of cases, due to excessive levels of free iron submitted in tissues, carcinogenic by the formation of reactive oxygen species). α1-antitrypsin deficiency, tyrosinosis, porphyria cutanea tarda, Clonorchis sinensis infection may also increase the risk of hepatocellular carcinoma development.

There have been identified certain factors which may decrease the risk of HCC in patients with cirrhosis : high serum retinol levels, high coffee consumption, alcohol cessation, clearance of HCV virus with treatment, iron depletion of hemochromatosis patients [5].

PATHOGENESIS

The pathogenesis of HCC is not fully understood, but most probably HCC results from activation of proto-oncogenes, deactivation of tumor suppressor genes (p53, pRb), changes in growth factors signaling processes (insulin-like growth factor-IGF, transforming growth factor-TGF), changes in telomeric length and

activity or microsatellite instability. Genetic injury may result from a variety of sources, such as HBV and HCV viruses. HBV is associated with a relatively high frequency of mutations as it replicates through RNA-mediated reverse transcription and the HBV reverse transcriptase (HBV-RT) does not have proofreading function. Unlike HBV, HCV is a single-stranded non-retroviral RNA virus which does not integrate into the host genome.

Although there have been identified multiple genetic abnormalities in the development of HCC, it is probably that the process is complex and genetic studies are continuing [1].

DIAGNOSIS

Hepatocellular carcinoma should be suspected in patients with previously compensated cirrhosis who develop decompensation, such as encephalopathy, ascites, jaundice or variceal bleeding associated with the extension of the tumor into the hepatic or portal veins or arteriovenous shunt induced by the tumor. Other uncommon presentations include: para-neoplastic syndromes – hypercalcemia (by PTH-like synthesis), erythrocytosis (by EPO-like synthesis), carcinoid syndrome, porphyria cutanea tarda, vascular angioma.

Diarrhea may be the reason for presentation to hospital, caused by cholestasis or the production of prostaglandins by the tumor.

Cutaneous manifestations include pemphigus foliaceus, dermatomyositis, Leser-Trelat sign (suddenly installed seborrheic keratosis, accompanied by freckles, very itchy).

Acute presentation is determined by spontaneous rupture of the tumor into the peritoneum or invasion of the liver capsule. In this case, the preferred treatment is the chemoembolization of the bleeding artery. Capsule invasion is causing severe pain, similar to biliary colic, lasting less than 24 hours.

In end stages, patients may present consumptive syndrome with impaired general condition, anorexia, weight loss and fatigue.

Physical examination can detect an abdominal mass and a bruit related to arterioportal shunting may be heard. A supraclavicular lymphadenopathy (Virchow-Troisier), Sister Mary Joseph or axillar lymph-adenopathies are rarely present [6].

Laboratory studies can show high levels of aminotransferase, but can be also normal. Alkaline phosphatase may be elevated in infiltrative tumor or if there is biliary obstruction due to malignancy. α-fetoprotein, the tumor marker most frequently associated with hepatocellular carcinoma (a glycosylated protein expressed in proliferating hepatocytes) has a sensitivity of 41-65% and specificity of 80-94% when the cut-off value is 20 ng/ml; levels higher than 400 ng/ ml are likely to be caused by hepatocellular carcinoma. AFP>1000 ng/ml associated with a liver mass is diagnostic for hepatocellular carcinoma. However, AFP level is elevated in only 60-70% of patients and false-positive results may occur during pregnancy, in active liver disease, certain gastrointestinal tumors and embryonic tumor. Additional studies of AFP have revealed that AFP has three glycoforms (AFP-L1, AFP-L2, AFP-L3) according to their binding ability to the lectin lents agglutinin (LCA). It has been shown that AFP-L3 exists only in the serum of patients with hepatocellular carcinoma at a cut-off value of 15%, with a sensitivity and specificity of 96.9% and 92%, respectively, in detecting hepatocellular carcinoma [7].

Des-gamma carboxyprothrombin (DCP-prothrombin,a protein induced by vitamin K-absence, PIVK-II) has been described as a protein produced by malignant hepatocytes. Different studies have shown than a combined analysis of AFP and DCP can lead to a better prediction in early stages of hepatocellular carcinoma [8]. Glypican-3, a member of the glypican famlily, has been revealed as a diagnosis marker, having the capacity to differentiate hepatocellular carcinoma from cirrhotic liver or benign lesion. It has been demonstrated that Glypican-3 and AFP together increase sensitivity and specificity for the diagnosis of small and unicentric HCC, respectively [9].

Heat shock protein 70 (HSP) – a protein produced by cells as a response to exposure to stressful conditions, may also be used as a marker for diagnosis in hepatocellular carcinoma [10].

The International Consensus Group of Hepatocellular Neoplasia recommends to define a pathological diagnosis of hepatocellular carcinoma if at least 2 markers are positive.

Imaging diagnosis

A minimum of 2 imaging exploration is required for staging and to confirm/exclude vascular invasion (ultrasound, CT with contrast, MRI); additionally is performed chest CT and bone scintigraphy if taken into account liver transplantation. In case of portal vein thrombosis associated with a small hepatic lesion, Doppler ultrasound is performed and thrombus punction ultrasound guided; the presence of thrombus exclude the possibility of radical treatment. Arterial signal into the thrombus indicate the tumoral etiology.

Abdominal ultrasonography has a 50% sensitivity in hepatocellular carcinoma detection for liver with advanced cirrhosis. Lesions under 2 cm can usually be detected.

Ultrasound appearance is variable. Lesions are usually hypoechoic. In large hepatocellular carcinoma, hyperechoic or heterogenic appearance is due to necrosis, hemorrhage or fat infiltration. Small hepatocellular carcinomas can be homogeneously hyperechoic and can be similar to hemangioma (due to a large portion of fat being present in the tumor) or can appear hypoechoic. Doppler ultrasonography can be used in the detection of portal vein, hepatic artery or inferior vena cava invasion. Portal venous invasion is more common in hepatocellular carcinoma, but hepatic vein invasion is more specific.

Small hyperechoic masses seen on ultrasound require further examination, because they can represent hemangioma (most frequently), metastatic disease or, less likely, hepatocellular carcinoma. Further imaging with CT scanning or MRI during dynamic contrast enhancement shows the typical peripheral, nodular contrast enhancement pattern of hemangioma. MRI or CT scanning can further characterize many nonspecific hepatic masses seen on ultrasonography.

CT scan – dynamic CT, spiral CT is the investigation of election for hepatocellular carcinoma diagnosis. The CT appearance of hepatocellular carcinoma is variable, depending on image phase and tumor size. The most common attenuation pattern is iso-hyper-iso-attenuation on prephase, arterial phase and venous phase, respectively; however, this pattern is common to other hepatocellular nodules, including regenerative and dysplastic nodules.

Unenhanced CT typically shows an iso-hypodense mass; for large masses central areas of necrosis may be seen.

In the hepatic arterial phase, nodules appear hyperdense (relative to hepatic parenchyma), as a result of hepatic arterial supply. Larger tumors may have necrotic central regions that are usually hypodense during this imaging phase. Neovascularity indicate the presence of inconspicuous lesions.

In the portal venous phase, small nodules may appear isodense or hypodense and larger nodules with necrotic regions remain hypodense.

In the delayed-postcontrast phase, small nodules may be inconspicuous on late phases.

Spiral-CT evidentiate 17% of lesions <1 cm, 29% of lesions between 1 and 2 cm and 63% of lesions higher than 2 cm.

MRI has higher sensitivity for focal hepatic lesions than CT.

Precontrast and postcontrast MRI has a 70-85% chance of detecting a solitary mass of HCC.

MRI can differentiate cirrhotic nodules from HCC: if the mass is bright on T2-weighted images, it is HCC until proven otherwise; if the mass is dark on T1- and T2-weighted images, it is a siderotic regenerative nodule or siderotic dysplastic nodule; if the mass is bright on T1-weighted images and dark or isointense on T2-weighted images, it is a dysplastic nodule or low-grade HCC [11].

Hepatic angiography.

Hepatocellular carcinoma is vascularized by hepatic artery and selective arteriography of superior mesenteric artery or celiac artery may identify the lesion. This is an invasive procedure used for hepatic chemoembolisation.

Liver biopsy.

For small lesions detected on ultrasound or CT, histological confirmation is very important. Biopsy is performed with ultrasound or CT guidance. There is a possibility of sowing on the needle path.

In present, the diagnosis of hepatocellular carcinoma is established by clinical examination associated with typical imaging aspect, with/without increased α-fetoprotein, histological confirmation not being absolutely necessary.

EASL 2016 recommend to perform liver biopsy for lesions with atypical imaging aspect and in non-cirrhotic patients [12].

DIFFERENTIAL DIAGNOSIS OF HEPATOCELLULAR CARCINOMA IN THE PRESENCE OF CIRRHOSIS

The major problem consist in the differentiation between hepatocellular carcinoma and a dysplastic nodule. Hepatocellular carcinoma appear hyper-vascularised compared to surrounding tissues.

For lesions higher than 2 cm identified in 2 different imaging studies, in the presence of cirrhosis, the diagnosis of hepatocellular carcinoma can be established. Also, if the lesion is identified in 2 different imaging studies and α-fetoprotein level is higher than 400 ng/ml, the diagnosis is very probable and histological confirmation is not really necessary [1].

SCREENING

Hepatocellular carcinoma screening is recommended in patients at high risk, such as male patients, HBV, HCV viruses, age > 40 years and chronic liver disease, especially cirrhosis and high grade dysplasia.

EASL 2016 clinical practice guidelines on the management of hepatocellular carcinoma recommend screening for patients with chronic HBV infection, even without cirrhosis, Asian males >40 years, females >50 years, patients with family history of hepatocellular carcinoma, African Americans >20 years, primary biliary cirrhosis stage 4, hemochromatosis, α1-antitrypsin deficiency.

Recommended screening methods are abdominal ultrasound combined with α-fetoprotein every 6 months. In cirrhotic patients, a nodule <1 cm detected must be supervised every 4 months for 1 year, than every 6 months.

For nodules 1-2 cm in diameter, the diagnosis is established by non-invasive criteria or histological examination.

Nodules higher than 2 cm may be diagnostic for hepatocellular carcinoma in case of typical aspect; for atypical aspect, histological examination is required [12].

TREATMENT OPTIONS

The treatment is established using the Barcelona-Clinic Liver Cancer (BCLC) staging system which defines very early stage cancer (single nodule,<2 cm, Child-Pugh A) as stage 0, early stage cancer (1-3 nodules, <3 cm each, Child-Pugh A-B) as stage A, intermediate stage for multinodular HCC (stage B), advanced stage which involves vascular invasion or extrahepatic spread (stage C) and terminal stage at patients with Child-Pugh C cirrhosis. Resection, ablation and transplantation is recommended for stage 0 and A, transcatheter arterial chemoembolization for stage B, Sorafenib – stage C and best supportive care for terminal stage.

Surgical treatment

Resection is curative, but limited in patients without cirrhosis or in the presence of cirrhosis and without portal hypertension. It is accepted as treatment for localized hepatocellular carcinomas. Intrahepatic recurrence is common, because the potential of neoplastic liver remain unchanged. The rate of recurrence at 5 years is almost 52 %. Partial hepatectomy is indicated in the absence of cirrhosis or in Child-Pugh stage A with normal portal pressure and normal bilirubin. The best results are obtained in patients with unicentrical disease, without vascular invasion, under 5 cm and with liver disease relatively inactive (5% of hepatocellular carcinomas). 5-year survival rate for curative treatment (resection, transplantation and local ablation therapy) is almost 80%.

Liver transplantation – the technique is successful in

selected patients, but it requires immunosuppressive treatment for life. It is indicated in patients with advanced cirrhosis (Child-Pugh B and C) who cannot survive on surgical resection. Liver transplantation can be applied independently on the liver stage disease and treat both hepatocellular carcinoma and neoplastic potential of cirrhotic liver.

Liver transplantation is indicated for unique tumors under 5 cm or <3 nodules (Milano criteria), each less than 3 cm.

It is difficult to elect between resection and transplantation for a tumor <5 cm. Altered liver function is in favor of transplantation.

Nonsurgical treatment

Chemotherapy

Sorafenib, a Raf-kinase and tyrosine kinase inhibitor, is indicated in patients with normal liver function (Child-Pugh A) and portal vein thrombosis, extrahepatic tumors and failure of other therapies. In patients with altered liver function, only best supportive care is indicated.

Local ablation-is potentially curative in patients with small tumors, <3-5 cm that are not candidates for resection or transplantation.

TACE (Transarterial chemoembolisation) – hepatic artery catheterization via the femoral artery or celiac axis allows the nutrient vessel embolization of tumor, and chemotherapeutic agents can be delivered in high concentrations. (Cisplatinum, Doxorubicim, foam gel, Epirubicin). Chemoembolization is indicated in unresecable tumors, patients with Child-Pugh A-B. The result is partial/total tumoral necrosis. The most frequent side effects are fever, nausea, encephalopathy, ascites and high levels of aminotransferase.

Percutaneous injection of ethanol (PEI) is efficient in 2-3 cm tumors (<5 cm), usually less than 3 nodules, even in the presence of advanced cirrhosis. The technique suppose the ethanol injection under ultrasound/CT guidance; outpatient treatment may be carried out 2 times per week, 3-15 sessions, using 2-16 ml of absolute alcohol. 3-year survival rate is 71% in patients with Child-Pugh A and 41% in Child-Pugh B.

Radiofrequency ablation (RFA) is a treatment that uses imaging guidance to place a needle electrode through the skin into a liver tumor. High-frequency electrical currents are passed through the electrode, creating heat that destroys the cancer cells. RFA is more effective than PEI in larger tumors (3-5 cm) and it requires fewer sessions. Recurrence rates are higher than in resection, but survival rate is similar to resection.

Trans-catheter arterial chemoembolization uses angiography and allows the nutrient vessel embolization of tumor. TACE is recommended in palliative treatment for unresecable tumors and in patients on transplantation list; the effectiveness of the method depends on the tumor dimension. TACE it is not recommended in the treatment of large and unresecable tumors.

CONCLUSION

In conclusion, hepatocellular carcinoma remain a fatal disease. All treatments used increases survival. Some studies have shown that there were no big differences between the results given by resection, transplantation and arterial embolization [13].

Lipid profile and comorbidities in patients with psoriasis vulgaris

Georgescu Mihaela[1], Poenaru Marcela[1], Ţoropoc Ionel[1], Costache Daniel[1], Morariu Silviu Horia[2], Richea Lorena[2], Badea Mihai Alexandru[2], Ţiplica George Sorin[3]

Abstract: *Background and Aim: Psoriasis is an inflammatory skin disorder with important influence on the lipid profile, insulin resistance and cardiovascular disease. The aim of this study is to compare the lipid profile of classical therapy versus anti-TNFs patients and asses the associated diseases.*
Methods: We conducted a prospective study. Patients' data were collected from two Romanian Dermatology Clinics, during the period January 2015 – June 2016. The patients were divided into two groups: study group (on TNF inhibitors) and control group (on classical treatment).
Results: The subjects in the study group had more associated diseases and much more patients suffered from dyslipidemia. There were not statistically significant differences in the lipid profile between the two groups. But eliminating patients treated with Acitretin and Methotrexate, a p-value of 0.0259 (significant statistically) was observed when comparing the values of triglycerides in the two groups.
Conclusions: We did not observe a beneficial effect of the TNF inhibitors therapy in psoriatic patients on the lipid profile. Subjects on biological treatment suffer from a more severe form of psoriasis vulgaris and associate much more comorbidities.

Keywords: *lipid profile, comorbidities, anti-TNF agents*.

INTRODUCTION

Psoriasis is a chronic, inflammatory skin disorder [1]. The inflammation predisposes to a pro-atherogenic lipoprotein profile, large vessel inflammation, and adipokine dysregulation [1] thus leading to insulin resistance and cardiovascular diseases [2]. There is a strong link between psoriasis and risk factors for metabolic syndrome (central obesity, insulin resistance [3], abnormal lipid metabolism [4], hypertension [5]. Patients with psoriasis have a more increased risk of developing atherosclerosis due to inflammation and dyslipidemia [4]. Moreover, lipid abnormalities may play an important role in the development of psoriasis [4].

The inflammation mediated changes at lipids and lipoproteins levels have more likely a role in protecting the host. The treatment of psoriasis was shown to lead to a normalization of the lipid levels [6]. TNF induces a reduction in cholesterols (especially HDL) by interfering with LDL receptors, Apolipoprotein A and B, and 7A1 and 7B1 cytochromes with no changes in HMG-Co reductase action [7].

[2] Mures County Clinical Hospital, Tg. Mures, Romania
[3] Colentina Hospital, Bucharest, Romania

In Romania, however, the inclusion criteria for biological therapies require previous two systemic non-biological therapies (retinoids, systemic glucocorticoids, methotrexate, PUVA, UVB narrow band).

Moreover, most of these therapies are known as lipid modifiers [4].

The aim of this study was to examine two groups of patients (biological versus non-biological therapy psoriatic patients) in terms of comorbidities and lipid profile.

MATERIAL AND METHODS

Study design

We carried out a prospective study. Patients' data were collected from two Romanian Dermatology Clinics: Dermatology Department, Carol Davila Emergency Military Hospital, Bucharest, (January – June 2016) and Dermatology Department, Mureş County Clinical Hospital, (January – December 2015).

All subjects had a physical examination. Body max index (BMI) was calculated as weight (kg)/height (cm²) (normal weight: 18.5–24, 9; overweight: 25–29, 9; class I obesity: 30–34, 9; class II obesity: 35–39, 9; class III obesity: ≥ 40). Each patient completed a DLQI form and a dermatologist filled the PASI form.

The data collected included (i) patients' demographic characteristics: date of birth, gender, weight, height, BMI; (ii) psoriasis-related data: type of psoriasis, current therapies (topical treatment, Methotrexate/ MTX, Acitretin, PUVA, UVB TL01, anti-TNFs: Infliximab original and biosimilar, Adalimumab, Etanercept); (iii) comorbidities, with an accent on metabolic syndrome (hypertension, diabetes mellitus, obesity); (iv) cholesterol/cho and triglycerides/TG levels.

Patients were divided into two groups: study group (biological therapy) and control group (topical treatment, Methotrexate, Acitretin, PUVA, UVB TL01).

All participants gave written informed consent.

Statistical analysis

Data were analyzed using 2017 GraphPad Software.

RESULTS

At the end of the follow-up period, 102 subjects were included for the analysis: study group – 53 patients: 39 males (73.58%) and 14 females (26.42%) and control group – 49 patients: 25 females (51.02%) and 24 males (48.98%).

The biological therapy patients were distributed as follows: Infliximab (9, 16.98%), Infliximab biosimilars (4, 7.54%), Entanercept (17, 32.07%), Adalimumab (23, 43.39%). Four subjects had a switch of anti-TNF therapy, two changed Infliximab for Etanercept, the other two switched Infliximab for Adalimumab. Only 16 (15.68%) patients out of the 102 achieved both PASI and DLQI equal to zero during the study.

Biological patients were screened for associated diseases. Table 1 includes the number/(%) and comorbidities.

Table 1: Comorbidities of biological patients

Associated diseases	Number of patients /(%)
HTA	10/(18.86%)
Diabetes mellitus type 2	3/(5.66%)
Obesity	40/(77.35%)
Latent tuberculosis	5/(9.43%)
Hepatitis VHB	1/(1.88%)
Herpes zoster	1/(1.88%)
BPOC	1/(1.88%)
Chronic bronchitis	2/(3.77%)
Hepatic steatosis	1/(1.88%)
Glaucoma	1/(1.88%)
Arthropathy	15/(28.3%)
Synovitis right knee	1/(1.88%)
Disc hernia	1/(1.88%)
Anemia	1/(1.88%)
Allergy to penicillin and erythromycin	1/(1.88%)
Renal litiasis	1/(1.88%)
Hidradenitis suppurativa	3/(5.66%)
Bipolar disorder	1/(1.88%)
Amputation of right police	1/(1.88%)
Thyroid nodule operation	1/(1.88%)
Cholecystectomy	3/(5.66%)
Appendectomy	2/(3.77%)

The subjects with criteria of metabolic syndrome were

41 (77.35%) with obesity, 3 (5.66%) had diabetes mellitus type 2, 10 (18.86%) with hypertension. Other comorbidities were previous surgery (cholecystectomy, thyroid nodule operation, appendectomy), infection (latent tuberculosis, hepatitis VHB, herpes zoster), accidents (amputation of right police), pulmonary disease (BPOC, chronic bronchitis), inflammatory disease (hidradenitis suppurativa), hepatic disease (hepatic steatosis), renal disease (renal litiasis), ocular disorder (glaucoma), skeletal problems (arthropathy, synovitis right knee, disc hernia), hematological disease (anemia), psychiatric disorder (bipolar disease), allergy to drugs (allergy to penicillin and erythromycin).

The classical therapy patients associated obesity – 20 (40.81%), diabetes mellitus type 2 – 3 (6.12%), hypertension – 4 (8.16%). Other associated diseases were: hematological (anemia, thalassemia), skin cancer, arthropathy, osteoporosis, Cushing disease, venous disease, operated pituitary gland (table 2).

Table 2: Associated diseases of control group

Associated diseases	Number of patients
HTA	4
Diabetes mellitus type 2	3
Obesity	20
Anemia	1
Thalassemia	1
Skin cancer	2
Arthropathy	9
Osteoporosis	1
Cushing disease	1
Operated pituitary gland tumor	1
Chronic venous insufficiency	1

Patients with psoriasis have an important weight problem. The normal weight patients in the study group represented 12 (22.64%) versus 16 (32.65%) control group patients. Increased BMI was found in 74 (72.54%) psoriatic patients. (Table 3)

Some patients on anti-TNFs required additional drugs for disease control. 10 (18.86%) biological therapy patients used only topical treatment versus the majority of control group – 45 (91.83%).

Table 3: BMI for the two groups

BMI	Study group	Control group
Normal weight	12	16
Overweight	20	20
Obesity class I	15	13
Obesity class II	5	-
Obesity class III	1	-

Methotrexate was prescribed to 6 (11.3%) patients in the study group and to 4 (8.16%) patients on classical therapy.

Retinoid (Acitretin) was used only in 1 (1.88%) biological patient versus 2 (4.08%) patients in the control group. (Tables 4, 5)

Table 4: Additional therapy of anti-TNFs patients

Patient	Additional therapy

47	0.1% mometasone furoate cream, 15% urea cream, emollient cream, Methotrexate
48	0.1% mometasone furoate cream, 15% urea cream, emollient cream, Methotrexate
49	calcipotriol and betamethasone gel, 15% urea cream, vitamin A, vitamin E, Methotrexate, PUVA

The lipid profile was screened in both groups of patients. But there was no difference between the two groups of patients. The p-value comparing the two groups of cholesterol (study vs. control) was 0.8674, and for the triglycerides groups (study vs. control) was 0.218. On the other hand, a significant statistically p-value of 0.0259 was observed when comparing the values of triglycerides in the 2 groups, but after eliminating the patients on Acitretin and Methotrexate.

We compared the cholesterol and triglycerides values from each group for patients treated only Methotrexate or Acitretin and the ones on anti-TNFs and Methotrexate or Acitretin, but no significant p-values were found.

We observed high triglycerides values in patients treated with Infliximab – 7 (58.33%) followed by Etanercept – 5 (35.71%) and Adalimumab – 4 (22.22%). The highest levels of cholesterol were observed in the Etanercept and Adalimumab subgroup 11 (78.57%). The others subgroups contained only small samples of patients. (Table 6)

The study group was divided into subgroups of years on biological therapy and the levels of cholesterol and triglycerides were compared.

Table 6: Patients with high lipid values divided into systemic therapies

Therapy	High cholesterol No/(%)	High triglycerides No/(%)
Infliximab (original + biosimilar)	2 (16%)	7 (58.33%)
Etanercept	11 (78.57%)	5 (35.71%)
Adalimumab	11 (61.11%)	4 (22.22%)
Adalimumab + Methotrexate	3 (75%)	3 (75%)
Etanercept + Methotrexate	2 (100%)	0 (0%)
Adalimumab + Acitretin	1 (100%)	0 (0%)
Methotrexate	2 (50%)	3 (75%)
Acitretin	0 (0%)	0 (0%)

The subgroup 4-6 years had the highest level of dyslipidemia as it can be observed in Table 7.

DISCUSSION

Analyzing the two groups, the patients on biological therapy seemed to have more associated comorbidities than the control group. Cardiovascular events appear more often in patients with severe (8) and therapy resistant psoriasis like the ones treated

with anti-TNFs.

The two groups showed a difference in the frequency of hypertension (study group – 18 (86%) vs. control group – 8 (16%)). Even though, in normotensive and rheumatoid arthritis individuals, Infliximab reduced blood pressure levels, we observed in our study that the anti-TNFs do not improve alone the blood pressure values in psoriatic hypertensive patients [9].

Table 7: Levels of cholesterol and triglycerides divided into subgroup of years of anti-TNF therapy

Years of biological therapy	High cholesterol	High triglycerides	Cholesterol %	Triglycerides %
≤ 3.5 years	7	4	13.20	7.54
4-6 years	22	15	41.50	28.30
7-8 years	2	2	3.70	3.70

Many studies observed that high blood pressure is more often noted in patients with psoriasis compared to the non-psoriatic population [10], especially psoriatic patients who were male, middle-aged and elderly people [11] as our study group (39 males (73.58%) versus 14 females (26.42%)). Men are more predispose to severe forms of psoriasis [12].

High blood pressure is independent associated with psoriasis [8].

Apparently, in psoriasis the pathophysiologic mechanisms for high blood pressure are related to the underlying autonomic nervous system dysfunction [13], elevated plasma renin activity, elevated angiotensin converting enzyme activity, and elevated endothelin-1, TNFG308A polymorphism [14].

Psoriasis is thought to promote insulin resistance by overproduction of Th1 cytokines [10]. An association can be observed between high levels of TNFα, IL6, IL17, leptin, and C-reactive protein, and increases in BMI, which contribute to alterations in insulin biochemical pathways, leading to insulin resistance, type II diabetes [15]. Our patients are overweight, dyslipidemic and topical corticosteroid users for long periods of time, more over they have an inflammatory disease which is pro-atherogenic. Although only 6 patients out of 103 were diagnosed with diabetes mellitus type 2, the screening is continuous, because psoriasis is an independent risk factor for type 2 DM, the risk being greater in severe disease. (Marius Irimie, 2015).

Most of our patients with psoriasis vulgaris are above normal weight (72.54%). It has been reported that psoriasis favors weight increase and obesity [15]. In obesity there is an unbalanced production of pro- and anti-inflammatory adipokines in obesity, leading to a chronic low-grade inflammation state, which seems to favor worsening of psoriasis lesion and a poorer response to treatment [16].

Although we did not evaluate the weight gain before and after anti-TNF treatment, several studies have reported an increase in weight and body mass index (BMI) with the use of anti-TNF agents (adalimumab, etanercept and infliximab) [9, 17]. Most of our patients in the study group are overweight (77.35%).

On the other hand, weight loss (greater than or equal to 5% of the initial weight) is associated with a higher success rate in achieving control of disease activity in patients with overweight or obesity with psoriatic arthritis treated with anti-TNF-α [9]. A study with patients on low-energy diet lost weight which led to significant reductions of several cardiovascular risk-associated factors, moreover the weight loss improved HbA1c levels by 0.7%, equivalent to reductions achieved by treatment with an anti-diabetic drug [18]. Moreover, the psoriatic patients with the lowest monounsaturated fatty acid (MUFA) intake presented the highest values of PASI score and inflammation marker [19].

The mean age of psoriasis patients in our study was 52.07 years similar to international studies, thus confirming the average age of type 2 psoriasis patients worldwide [20]. Moreover the biological patients are the ones that do not respond to classical therapy

suggesting the severe form. The equal distribution in the classical therapy group can be due only to a mild form of disease.

Between the two groups there were not statistically significant differences in the lipid profile. Our results are similar with those of [21], their psoriatic patients treated with etanercept, adalimumab, or infliximab (each patient serving as their own control), did not present a significant change in total cholesterol, LDL and triglycerides. On the other hand, a p-value of 0.0259 (significant statistically) was observed when comparing the values of triglycerides in the two groups (eliminating the patients on Acitretin and Methotrexate).

We discovered that patients with 4-6 years of anti-TNF therapy were the majority group with dyslipidemia. However, the study of Ehsani et al. demonstrated an insignificant 5% increase in LDL and triglycerides after 24 weeks of treatment with anti – TNF agents [7], but all the changes in lipid profile by biological therapy are temporary, and the negative feedback will balance these changes over time [7]. Others have proven that patients with long term psoriasis have an increase in the serum total cholesterol levels and triglyceride levels [22]. Several authors found increased cholesterol levels (more than 5 years), but the lipid profile changes from the early stage to the late chronic stage of the disease. In contrast, Jorge Santos-Juanes et al. did not find a relationship between lipid levels and disease duration [23]. Maybe lipid profile abnormalities might be genetically determined rather than acquired [8].

Comparing only patients on MTX or Acitretin versus patients on anti-TNFs and MTX or Acitretin we did not observe a significant statistically important difference. But in similar studies there was a significant increase in triglycerides in patients treated with TNF inhibitors + MTX compared with patients treated with MTX alone. In our study, the highest triglycerides levels had patients on Infliximab – 7 (58.33%), followed by Etanercept – 5 (35.71%) and Adalimumab – 4 (22.22%). Concerning cholesterol levels were higher in Adalimumab and Etanercept – 11 subjects (61.11%; 78.57%). The patients on systemic classical treatment (Methotrexate or Acitretin) or on anti-TNF + MTX/ Acitretin were too few to have statistical significance [21].

Our control group (excluding MTX and Acitretin) showed increased cholesterol (26/53.06%) versus triglycerides levels (6/12.24%). Other studies showed that TG levels were significantly higher in psoriatic subjects than control groups [24].

We did not exclude patients on Methotrexate and Acitretin.

These may cause or influence the dyslipidemia. Recent studies proved that retinoid acid treatment could produce unsaturated fatty acids and induce triglyceride breakdown, bile acid secretion, lipolysis, and retinoids elimination. But, retinoid x receptor α deficiency might induce the synthesis of saturated fatty acids, triglyceride, cholesterol, bile acids, and retinoids [25]. Retinoids, especially Acitretin increase triglycerides levels [26], but also a mild and transient reduction in HDL levels and insulin sensitivity [27].

Regarding MTX, there are conflicting studies on the effect of Methotrexate on the lipid metabolism. The HDL profile function is favorable influenced by Methotrexate [28], Methotrexate has an anti-atherogenic potential [29] with cardioprotective properties [30]: tendency to decrease the risk of heart failure [9], a lower incidence of vascular disease (cardiovascular, cerebrovascular and arteriosclerosis) [17]. But it has been proven that cholesterol, LDL cholesterol and HDL cholesterol are increased short-termed after the initiation of Methotrexate therapy [31].

CONCLUSION

Our study did not show a positive effect of anti-TNF therapy in psoriatic patients on the lipid profile. Most likely, the abnormalities of the lipids are due to genetically inherited mechanisms. Our patients on biological therapy have a more severe form of psoriasis vulgaris, with many comorbidities.

Management of burning mouth syndrome (BMS) in patients with diabetes mellitus

Elena C. Coculescu[1], Ioanina Părlătescu[1], Carmen Gheorghe[1], Șerban Țovaru[1], Bogdan I. Coculescu[2,3]

Abstract: *Unlike the therapy of primary BMS, the treatment of secondary BMS benefits, in addition to symptomatic therapy, from the possibility of using means and methods to correct biological disturbances and/or morphological, psycho-emotional changes respectively. The use of these therapeutic means in secondary BMS is recommended to be established as a first step of therapeutic conduct. Their success is reflected in homeostasis restoring, correcting morphological and functional changes of the field, which frequently leads to no longer use prescription of symptomatic treatment.*

DEFINITION

The International Association for the Study of Pain (IASP) defines burning mouth syndrome (BMS) as a "distinct nosological entity" characterized by "oral sensation of burning or pain, persistent and non-remitting in time in the absence of clinical objective changes of the mouth mucosa" [1]. A relatively similar vision is supported by Grushka (2014). BMS defining a sensory sensation, the author admits that this is manifested mainly by: a) subjective characteristics: changes in taste perception; bilateral burning sensation associated with altered taste mouth; sensation of "dry mouth", although salivary flow is not reduced; perceived foreign body in the oropharynx and b) objective criterion: the oral tissues with clinically normal aspect. The author specifically mentions that the 4 subjective lists, encountered in BMS come forth from the absence of results after an objective clinical exam, a defining element for this condition [2].

EPIDEMIOLOGY

Setting the epidemiology of BMS is difficult and imprecise because there is no universally accepted definition. The various epidemiological studies often refer to different clinical entities in which oral mucosal lesions lack [3]. This disease has a high rate that varies according to the studies from 0.7% to 14.8 - 15% [3,4,5]. The prevalence of painful syndrome in the Service of Oral Pathology of the Faculty of Dental Medicine - "Carol Davila" University of Medicine and Pharmacy, Bucharest (Romania) is 16.23% [6].

ETIOLOGY. PREDISPOSING FACTORS

Pathogenic, sex, age, menopause can be considered contributing factors. Therefore:
1. Although it was observed in any age group between 27-87, BMS has a clear predisposition related to age. The average age of reporting the disease is 61 [2]. BMS rarely occurs before the age of 30 [7].
2. Sex is also placed between contributory factors. The women are 2.5 to 7 times more frequently affected than men.
3. The body functioning as a whole, at menopause, besides circulating electrolyte changes, it suffers from other disturbances such as:
a) Lipid disorders with consequences in the development of atherosclerosis;
b) exacerbated production of ROS/RNS, including liquid in the gingival sulcus (where ROS = reactive oxygen species, and RNS = reactive nitrogen species);
c) changes in the hormonal constellation at menopauses the quantity of estrogen become responsible for the development of female cardiovascular pathologies same as men.

Data from the literature considers that up to 90% of the female patients with BMS are around menopause, the onset of symptoms characteristic of peri-menopausal period taking place three years before and 12 years after climax [8].

The explanation for BMS distribution predominantly in women during perimenopause, according to Woda et al. (2009) is that BMS is the result of hormonal changes (hypo-estrogenism) in women during menopause, which often associates with metabolic disorders and neuropsychological chronic anxiety or stress. Mental disorder in menopausal women explains anxiety and depression from BMS [9].

4. Another pathogenic explanation takes into consideration the interrelationship taste-saliva-pain. Laboratory tests showed that female patients with disorders in climax present a growth of salivary phosphate concentrations, proteins, Na, K+, Ca2+ and Mg2+. The referred electrolyte disturbances trigger the disruption of the membrane potential, including those of the cells involved in collecting taste excitations or cells responsible for saliva secretion [10].

Certain hormonal changes (hypoestrogenemia, diabetes mellitus, hypothyroidism, thyroid dysfunction type) and functional morphological and immunological disorders affecting the endocrine glands were also among factors described as possible cause of this disorder [11]. Regarding the relationship between diabetes and BMS various assumptions were formulated, including the existence of metabolic changes in the mouth due to peripheral neuropathy, which can generate among other disturbances the hypo-function of the salivary glands, thus reducing the secondary salivary flow [3,12,13].

The mode of action of psycho-neuro-endocrine factor is even more difficult to explain since it has been shown that patients presenting BMS have a greater tendency to somatization and to develop psychiatric symptoms [11]. For this reason the theory was accepted that burning mouth syndrome is a form of neuropathic pain [14]. The neuropathy mechanism in the pathogenesis of BMS is still controversial, the expert literature admitting the possibility of dysfunction via peripheral or central reflex arc and cortical excitation [8,10].

BMS SYMPTOMS

Subjectively, patients describe the syndrome BMS as the presence of oral mucosa burning sensation, the most common manifestation present in the disease. Other features of the pain in this syndrome are itching sensation, numbness, impaired taste (taste “spicy”), dry mouth etc. As topography, the symptom is located almost constantly close to the lingual mucosa (especially in the front third) and the lip. Recently, Demarosi (2013) stresses however that it is not possible that all the oral mucosa could be involved without being identified any precise anatomic distribution [3].

Even since 2003, Scala et al. underlined the semiotic nature of BMS as being more complex, consisting of main and associated symptoms:
a) The main symptom is a triad, consisting of:
1. Pain in the oral mucosa: burning, stinging, tingling, swelling;

2. Dysgeusia (altered taste): the persistence of a certain flavor/taste perception alteration;
3. Xerostomia, with dry mouth.
b) Other associated symptoms: thirst, headache, pain in the temporomandibular joint (TMJ), tenderness/ pain during mastication and/or in some regions of the neck suprahyoid or shoulder level muscles [15].

The amount of positive clinical examination in the diagnosis and any associated distress, which act as causative factors in BMS syndrome

BMS diagnosis is essentially one of exclusion [16]. It is based on a historic and very thorough clinical examination. An accurate diagnosis requires careful investigation of BMS medical history of each patient (such as a preexisting condition at the oral mucosa level, malnutrition, cerebral dysfunctions or drug intoxication) [17,18].

1. The contribution of general clinical examination in the diagnosis of BMS

At their first visit at the dentist's, patients frequently report present disorders and diseases already diagnosed under therapy. When there is a suspicion of disease present and undiagnosed, the patient is advised to consult a physician in the respective domain [19].

2. The role of local clinical examination in the diagnosis of BMS

Local clinical examination often does not reveal any changes. Sometimes clinical examination can detect minor changes or variations of normality: fissured tongue, exfoliative glossitis, depapillations of various origins, geographic tongue or coated tongue [16].

If physical examination reveals the absence of clinically obvious lesions on the oral mucosa, it is reasonable to suspect that intraoral burning is a possible indicator of a systemic disorder [3].

Identifying the possibility of the existence of systemic diseases associated with or responsible for installing the BMS syndrome is by clinical examination and by performing general laboratory or laboratory tests [16].

THE MAIN THERAPIES EMPLOYED IN THE BMS

Based on a comprehensive assessment of the patient's disease state that integrates general clinical examination results, psychiatric/psychological balance and the local dental examination, a therapy in BMS is set. The characteristic of glossodynia treatment is its individualization and adapting to each individual case [19].

Primary stage in establishing BMS therapy requires the differentiation of the primary from the secondary. This is because if the balance sheet allowed the identification of predisposing and etiologic factors, therapy will target their harmful action through appropriate specific methods.

Clinical attitude to be adopted to establish the diagnosis and clinical form of BMS is summarized in figure 1. Schematic representation is useful because it allows to facilitate the understanding of therapeutic medical conduct to follow. According to Demarosi (2013), clinical, biochemical and hematological test results represent two phases of special importance in the etiological diagnosis of the BMS [3].

The therapy goals of the BMS syndrome are administered to target a triple purpose:
1) Improvement of symptoms;
2) Correction of biological and/or morphological disturbances (if there are), commonly referred to as correction therapy;
3) Changes in psycho-emotional therapy [3].

Symptomatic treatment

Symptomatic treatment is similar in both cases of BMS (idiopathic or secondary). While pain is a symptom of many chronic diseases, persistent pain should not be regarded simply as a symptom. Pain itself can become a disease where pain signals origins fail to be controlled due to deterioration of the pain alarm system, leaving the patient with persistent pain. Whatever the cause, chronic pain can transcend ordinary physical pain. Persistent pain interferes with daily life, other important relationships and puts a mark on the mind, body and spirit of the BMS patient. The pain and related problems (e.g., medication side effects, depression and anxiety) can be best managed

using a complex program of integrative treatments tailored to each patient. The name of integrative treatment derives from the means/method by which it is achieved, the approach of a "multi-modal" one.

Ethiological diagnosis (secondary BMS)
Replacement therapy
Symptomatic therapy

The method involves combining treatments from conventional medicine with those of complementary and alternative therapies. Scientifically, for the efficiency of the latter, evidence have been provided for both the quality and safety of the therapy. In this category, the treatment of patients with BMS can use homeopathic products, cognitive-behavioral methods, aromatherapy, herbal extracts, vitamins, dietary supplements, some combination of minerals etc. [21,22]. Also, acupuncture as an adjunctive therapy method is referred to in the expert literature as being beneficial for the relief of symptoms in patients with BMS [14].

Generally speaking, it is acceptable that the treatment of idiopathic BMS is essentially a symptomatic treatment. In the context of such therapy, the dentist has available a number of symptomatic therapies that can be administered by the general or local means with topical use. Some of these are summarized in the table shown above. The purpose of a symptomatic therapy aims at either improving the intensity of symptoms or halting the clinical manifestations. The results are uncertain, including failure.

Therapeutic strategies include benzodiazepines (clonazepam), tricyclic antidepressants (amitriptyline), opioids (gabapentin), selective inhibitors of serotonin receptors (paroxetine and sertraline), capsaicin topical/systemic, alpha-lipoic acid (neurological antioxidant) hydrochloride, benzydamine 0.15%, hormone replacement therapy, vitamin supplementation and/or zinc, iron and psycho-cognitive therapy [3].

Tricyclic antidepressants (amitriptyline/doxepin/ nortriptyline) are extremely useful for patients with chronic pain. Although developed for the treatment of depression, they have a spectrum of biological activities depending on the dose, including inducing analgesia in a variety of clinical conditions. Although the mechanism is not known, the analgesic effect of antidepressants have a more rapid onset and occurs at a dose lower than that typically necessary to treat depression. The maximum effect is achieved by tricyclic antidepressants in patients with chronic pain who are not depressed, reduced pain being a certainty. Anticonvulsants (carbamazepine) and tranquilizers (clonazepam) are particularly useful for patients with neuropathic pain [23].

Capsaicin, a substance extracted from red peppers, is used for its revulsive and analgesic action. Capsaicin is specifically detected by the "transient receptor potential vanilloid receptor" (TRPV1) distributed in the oral mucosa. The explanation is that the capsaicin molecule is a selective agonist vanilloid receptors TRPV1. Binding means stimulating the receptor, which is found in the nociceptors (pain receptors) in the oral cavity. Overstimulation of TRPV1 receptors make them become "desensitized", no longer able to respond to the stimuli that normally cause pain in patients with peripheral neuropathic pain [24].

Topical application of capsaicin has been shown to sometimes be useful in some pain syndromes, in particular for relieving the symptoms of herpes neuralgia or diabetic polyneuropathy hyperalgesia [25].

Similar conclusions on the effectiveness of topical application of capsaicin (0.02%/0.002%) in BMS are made by Silvestre et al. (2012) and Spanemberg et al. (2011) [26,27].

Other authors speak of the efficacy of capsaicin. Spadari et al. (2014) reported a success rate of over 70% for each control visits after 1, 3, 6 and 12 months of topical therapy (as by rinsing the mouth with a solution of capsaicin 3 times/day) [28].

Among the most widely used symptomatic therapies for BMS are salivary substitutes, from the most simple and economical specific physiological solution to gel. Their use is motivated by the fact that xerostomia is a frequent syndrome in patients with BMS [3].

Grushka (2014) suggests that treatment involves a combination of several BMS drugs that act together, increasing each other's effect (they are given together as dose so that a low-dose should enhance the action). From such an attitude, “low dose” can achieve favorable results on major symptoms present in patients. Achieving success involves on the one hand an individualized (personalized) therapy, on the other successive explorations, to identify the effective drug combination. Based on the results of his studies, Grushka (2014) admits that ⅔ of the patients respond to the treatment aimed at suppressing the effects of benzodiazepine receptor agonists group GABA-A and inhibition of pain. The combination drug likely to complete such a success is a triad of medications: clonazepam 0.5 mg before bed + 10 mg amitriptyline + gabapentin 100-300 mg 3-4 times +/or 25-75 mg Pregabalin 3-4 times daily. Again Grushka (2014) states that zinc therapy is effective in taste changes, prescribing zinc gluconate 50 mg 1-3 times a day for a period of 3-4 months [2].

In conclusion, according to the expert literature, the current level of knowledge about the disease does not include any certainly effective treatment for primary BMS.

Treatment of secondary BMS

According to Ţovaru et al. (2015), for the treatment of secondary BMS the major objectives are:

• detection and treatment of general factors involved in the emergence of glossodynia (anemia, vitamin B deficiency, diabetes, autoimmune disorders of the digestive tract, disorders during menopause, and esophageal reflux caused by gastric hyperacidity);

• detection and removal of the local causes of BMS (incorrect prostheses, changed vertical dimension of the lower floor of the face, improper dental alloys, chronic mucosal infections – for example, Candida – contact allergies, dry mouth, migratory glossitis;

• detection and treatment of coexisting psychiatric disorders (anxiety neurosis or depression, with stress, chronic states of conflict, emotional pressure, cancer-phobia) [19].

Achieving this objectives requires expert advice and patient's hospitalization for the neuropsychological disorder, often lasting for years.

Etiological treatment

A priori, BMS secondary treatment is etiologic, addressed to fight against the general and local factors that maintain the syndrome. The success of etiologic therapy is dependent on the precision with which the causative factor was identified [8,19]. Thus, in the case of the presence of allergic contact reactions, simply removing the suspected allergen (e.g., the material / dental alloy) determines remission of the symptoms of BMS.

If the necessary examinations revealed the presence of anemia, therapy should be prescribed to correct hemoglobin assets and deposits of iron and vitamin B12. Completion of these deposits is mandatory because suppressing the substitute anti-etiological treatment after restoration of erythrocyte hemoglobin level, allows a recurrence of anemia after a certain period of time.

Etiological treatment is required in other cases of BMS secondary diseases such as diabetes mellitus, gastric ulcer, gastro-esophageal reflux disease, mycosis, and the burning mouth is one of the manifestations of

these disorders [3].

Psychological and psychiatric treatment

The second place in the treatment of secondary BMS is psycho-pharmaceutical correction. Frequently, symptomatic treatment [3] is no longer resorted to.

Psychological and psychiatric treatment in the syndrome of secondary BMS is applied not only to the patients with psychiatric disorders or behavioral disorders diagnosed during the first medical checkup, but also to patients who do not respond to dental treatment. For this purpose, patients are directed to consult a specialist who would in fact perform a reassessment if the psychotherapeutic treatment is not appropriate to be set [3,29].

Specialized treatment is achieved by two means:

a) psychotherapy (psychological exam);

b) with drugs, therapy monitored by a psychiatrist;

Psychological treatment aims at controlling and alleviating the mental disorders that occurred. Typically, psychological treatment complements the psychiatric one, but it is the first to start with, especially in patients who have problems with mental BMS, such as those with dental treatment failure. Results of consequent studies have concluded that pharmacological products such as benzidamine-HCl solution, sucralfate, antihistamines, lidocaine, capsaicin have not shown significant improvement statistically [2,3,16].

Frequently followed conduct is the psychoanalytic association with administration of specific psychotropic medication (anxiolytic, antidepressant). The usefulness of psychotherapy is to reduce symptoms, if there is a psychological component to glossodynia [19].

Counselling treatment

BMS syndrome treatment conduct includes counselling, preferably applied by a physician demonstrating empathy for the patient. The purpose of counselling is to provide the patient information and explanations about the sickness, benignity of the lesion, its correlation with notions of its correlation with field (age and sex). These patients should always know that their disorders are often related to stress and that if they make it go away, at least in part their suffering can diminish [3].

The doctor should always have the status of patients with BMS, the suffering and disease, so they have to devote the necessary time to communicate and discuss the patients' problems. This is because one of the major concerns of patients with BMS is to undergo a treatment to alleviate the symptoms [3].

During counselling sessions the BMS patient will be informed about the need to respect therapeutic indications, even if obvious improvements do not occur. Also, we will clarify that for the relief of symptoms, duration of treatment is for months/years.

Starting from his own medical experience, Demarosi (2013) states that patients rarely comply with prescribed BMS treatment, the recommended therapy is often performed incorrectly and doctor visits are random. Simultaneously, the patient will be clearly advised that the outcome of the treatment consisting in improvement or even the disappearance of the disease is often only temporarily effective [3].

Since the treatment of BMS is generally unsatisfactory even if it is appropriate, and the pain is chronic, it is necessary that patients be counselled with correct information on expectations that are to be understood realistically. Otherwise, the patient loses confidence in his regular doctor and becomes psychotic, going from doctor to doctor.

EVOLUTION AND PROGNOSIS IN BMS SYNDROME

Sardella et al. (2006) in a retrospective study of 18 months showed that 28.3% of the BMS (basic form) cases registered moderate improvement, 49% not any significant change, 18.9% of the cases presented a worsening of symptoms in patients who have not received any treatment. Spontaneous complete remission is rare and has been reported by the same team in 3% of cases investigated over a period of 5 years [30,31].

Cure rates measured in glossodynia of type I and II were almost comparable (61% versus 59%). 70% of all

cases that have not responded to treatment present associated psychiatric disorders [19].

Idiopathic nonspecific painful syndromes are most rebellious to treatment. Some cases even exclude any possibility of allopathic treatment, in which case additional treatment, such as acupuncture is resorted to (14). Frequently, the results of acupuncture are not always stable, and in some cases a patient can get addicted to this kind of treatment [19].

In other words, where allopathic treatment + psychological + counseling fail, acupuncture may be used with relative efficacy and limited duration, which requires to repeat the complementary procedure.

In another study, a group of 91 patients with BMS symptoms were analyzed and it was concluded that in a small number of patients symptoms may resolve spontaneously within five years from the onset. Moreover, a partial improvement was observed in 38.4% of these cases under various treatments (for example, clonazepam in local administration). This rate of improvement is greater (up 61.7%) when patients were administered clonazepam locally associated with psychotherapy [32].

Fenelon et al. (2014), evaluating the results of short-term therapy with clonazepam versus amitriptyline in the pain relief of BMS highlighted that after 6 weeks of treatment there was an improvement in the symptoms of pain in both situations, noting that the effect of amitriptyline was lower than that of clonazepam. To explain such particularity of the therapy, the authors imply a slow onset of action of the first drug. After 3 months, the results were similar in the two groups of patients evaluated [33].

New synthesized oximes active in nerve agents' hazards

Mihail S. Tudosie[1], Bogdan Patrinich[2], Andreea R. Negrea[3], Cristina A. Secară[2]

Abstract: *Object: The aim of the study is to select the most active new imidazolium-quinuclidinum-oxime, from some similar chemical compounds synthesized in our chemistry department, with sufficient efficacy to decrease the acute toxicity of neurotoxic organophosphates known as nerve agents. Method: The experimental study consist in vivo testing the antidotal efficacy of obidoxime and of selected imidazolium oximes synthesized in our chemistry department. Each oxime was included, by equimolar replacing the obidoxime, in an antidotal formula, which also contains atropine. The above mentioned formula containing atropine and obidoxime was used as reference. The protective ratio, defined as the ratio between the lethal median dose of the poisoned and treated study group and the median lethal dose (LD50) of the poisoned and untreated study groups was one of the used parameters in order to select a new active chemical structure in counteracting the neurotoxic organophosphorus compounds acute toxicity. Another studied parameter was the erythrocyte acetylcholinesterase value measured in whole blood 24 hours after exposure. Results: The protective ratio against an organophosphorus compound were the follow: obidoxime chloride: 2; 1,3-dimethyl-2-hydroxyethyl-imidazolyliodide: 1,75;3-oxime-[3-(2-hidroxyimino-methyl-1-imidazolyl-)-2oxapropyl]quinuclidin-dichl-oride: 2,5; 1-methyl-quinuclidin-3-iodide: 1,5. The erythrocyte acetycholinesterase main values were the following: the unpoisoned and untreated study group:3,45 ±0,13mmol/dl; the poisoned and untreated study group: 0,89 ±0,09 mmol/dl; the poisoned and 3-oxime-[3-(2-hidroxyimino-methyl-1-imidazolyl-)-2oxapropyl]quinuclidindichloride treated study group:2,89 ±0,11 mmol/dl; the poisoned and obidoxime treated study group: 2,53±0,15 mmol/dl. Conclusions: 3-oxime-[3-(2-hidroxyimino-methyl-1-imidazolyl-)-2oxapropyl] quinuclidindichloride synthesized in our chemistry department, has shown a better protective ratio and a more prolonged surviving time than the reference (obidoxime). It has shown the best AChE reactivation of all the synthetized compounds. This compound can be a cheap and good option for replacing obidoxime in the antidotal formula active in nerve agent exposure.*

Keywords: *obidoxime chloride; 1,3-dimethyl-2-hydroxyethyl-imidazolyl-iodide;3-oxime-[3-(2-hidroxyimino-methyl-1-imidazolyl-)-2oxapropyl] quinuclidin dichloride; 1-methyl-quinuclidin-3-on-iodide; organophosphorus compounds; nerve agents*

INTRODUCTION

Strategic expert analyzes have shown that in the next period, there may be international conflicts, amplifying the risk of attempts to use highly toxic chemicals as weapons of mass destruction.[1]

Romania through its geostrategic position, being the member of NATO, can provide a better potential target of such actions.

Neurotoxic organophosphorus compounds (sarin, soman, tabun, most insecticides) are chemical compounds, phosphonic acid esters with central and

[1] Carol Davila University of Medicine and Pharmacy, Bucharest
[2] Military Medical Research Center, Bucharest
[3] Intermedica Healthcare, Bucharest

peripheral properties, acetyl-cholinesterase and butyryl-cholinesterase irreversible inhibitors with toxic effects on smooth and striated muscles and central nervous system.[2-4]

They were registered on the list of substances to be destroyed in accordance with international regulations (Convention on the Prohibition of Development, Production and Stockpiling Chimice-Geneva).

Although banned by international conventions, these toxic substances have been used in terrorist attacks against civilians (Tokyo 1995 Halabja in 1987, Anfal-1988). In this context geostrategic and due to soaring use of organophosphorous insecticides, development of medical measures to protect against the lethal toxicity is one of the priorities of research within specialized programs of NATO (NBC – Science for Peace) and European Union (Chemical Program Weapons, Monitoring and Protection, created in the OPCW).

The acute toxicity of organophosphorus compounds known as nerve agents mainly result from their action as irreversible inhibitors of acetylcholinesterase (AChE). They suffer some conformational and chemical changes, resulting a phenomenon known as "aging", whose speed of appearance is directly proportional to the toxicity of compounds.[5,6]

Accumulation of acetylcholine stimulation leads to persistent cholinergic muscarinic receptors that trigger the syndrome whose symptoms include miosis, salivation, bronchial hypersecretion, bradycardia, bronchoconstriction, hypotension and diarrhea.[7]

Another effect of organophosphate anticholinesterases is the desensitization of nicotinic receptors followed by overstimulation, translated by skeletal muscle twitching and subsequent paralysis.[8] Central nervous system toxic effects include anxiety, restlessness, confusion, ataxia, tremors, convulsions, paralysis, cardiorespiratory effects and coma [9].

The treatment of nerve agents poisoning is based on an antimuscarinic agent (atropine), and an acetyl-cholinesterase reactivator called oxime according to its chemical structure. Atropine blocks the effects of accumulated acetylcholine resulting overstimulation of muscarinic receptors.[9,10]

Acetylcholinesterase reactivators dephosphorylate the acetylcholinesterase – organophosphorus complex, reactivating the enzyme activity.[11] The early appeared seizures were counteracted by benzodiazepines.

Currently available oximes (pralidoxime, obidoxime), have been shown to be less effective against one of the most toxic nerve agents (soman tabun). There is a strong interest in developing new, more potent acetyl cholinesterase reactivators with oxime structure.[12]

The present paper represents an in vivo screening study in selecting more potent chemical compounds, active in counteracting the nerve agents acute toxicity. The paper describes an experimental test of antidotal efficiency of some compounds containing imidazolium, or quinuclidinium rings, which equimolar replace obidoxime chloride in the antidoltal formula.

The results were expressed as the protective ratio representing the ratio between the DL50 of the neurotoxic compound administred to the poisoned and treated rat study group and the DL50 administered to the organoposphate compound of the poisoned and untreated study group.

MATERIAL AND METHODS

Chemicals

- obidoxime chloride (CAS number 111-90-9);
- atropine sulphate (CAS number 5908-99-6) were purchased from Sigma Aldrich;
- diclorvos (PESTANAL CAS number 62-73-7) were purchased from Sigma Aldrich.
- the experimentally tested quinuclidinium-imidazolium oximes were synthetized in the chemistry department of Medical Military Research Center.

Animals

Male Wistar rats (150-200g) were maintained on rice husk in polypropylene cages. Wistar free access to water and rodent pellet food. The study was

approved by the Ethical Committee on Animal Experimentation.

Acetycholinesterase measurement method: Elisa kit.

The kit is a sandwich enzyme immunoassay for in vitro quantitative measurement of Acetylcholinesterase in human serum, plasma and other biological fluids.

Target Information: Acetylcholinesterase hydrolyzes the neurotransmitter, acetylcholine at neuromuscular junctions and brain cholinergic synapses, and thus terminates signal transmission. It is also found on the red blood cell membranes, where it constitutes the Yt blood group antigen.

Figure 1: The chemical structure of the in vivo tested compounds as acetycholinesterase reactivators

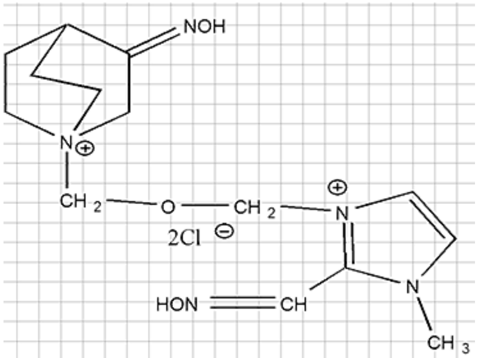
1,3-dimethyl-2-hidroxyethyl-imidazolyl-iodide



3oxim[3(2-hidroxy-iminomethyl-1-imidazolyl)-2oxapropyl] quinuclidine dichloride

Treatments

120 Wistar rats were divided into 12 groups, each, including ten rats as follows:

- 1st group: control group unpoisoned, untreated
- 2nd group: poisoned with diclorvos (1,5 DL50) and untreated;
- 3rd group: poisoned with diclorvos (1,5 DL50,) after one minute, were administered the antidotal formula including atropine (2mg) and obidoxime chloride (250 mg);
- 4th group: poisoned with diclorvos (1,5 DL50), after one minute, were administered the antidotal formula including atropine (2 mg) 1methyl-quinuclidine 3-on iodide in an equimolar dose with obidoxime chloride (78,5 mg);
- 5th group: poisoned with diclorvos (1,5DL50,) after one minute were administered the antidotal formula including atropine (2 mg), 1,3- dimethyl-2-hidroxy-ethylimidazolyl iodide in an equimolar dose with obidoxime chloride (61,94 mg/kg);
- 6th group: poisoned with diclorvos (1,5 DL50), after one minute, were administered the antidotal formula including atropine (1,5 mg) and 3oxim[3(2-hidroxy-iminomethyl-1-imidazolyl)-2oxapropyl] quinuclidine dichloride (118 mg/kg).

The above mentioned oximes were experimentally tested against 1.5, 1.75, 2, 2.5, DL50.

24 hours after poisoning mortality, protective ratio was registered and erythrocyte achetylcolinesterase activity values were measured.

RESULTS

The aim of the study is to evaluate the most active newly synthesised imidazolquinuclidine-oxime with the great efficacy in reactivating the phosphorylated acetylcholinesterase through some similar chemical compounds synthesized in our chemistry department, able to decrease acute neurotoxic compounds toxicity.

The protective ratio of the obidoxime and experimentally tested formulas correlated with their efficacy as acetylcholinesterase reactivators are represented in the Table 1.

The 3 oxim[3(2-hidroxyiminomethyl-1-imidazolyl)-2-oxapropyl] quinuclidine dichloride protective ratio correlated with its acetylcholinesterase reactivator activity is greater than the obidoxime, resulting a

better antidotal efficacy.

Statistical analysis Student's t-test probability associated with statistically significant differences between mean values of erythrocyte acetyl-cholinesterase between the control study group and the poisoned and treated study groups is represented in tables 2-7.

The poisoned and untreated group statistically significantly differs from normal in terms of the acetylcholinesterase inhibition.

Neurotoxic organo-phosphorous compounds cause in the intoxicated group and untreated study group an acetylcholinesterase inhibition of 75.08%, incompatible with survival.

Obidoxime and new synthesized imidazolium-quiniclidinium oximes highlighted new capabilities of acetylcholinesterase reactivation correlated with the protection index.

3-oxime compound [3-(2-hidroxyiminomethyl-1-imidazolyl)-2oxapropyl]-quinuclidine-dichloride-quinuclidine 3-on iodide revealed a protection index bigger than other obidoxime and other imidazolium compounds studied.

Explanation of this is that the quinuclidine ring, by its position intensifies allosteric oxime group (Table 1).

Tables 2-7 reveals that the intoxicated untreated control group differs statistically significantly from normal and so the intoxicated study groups were treated with different therapeutic formulations.

Table 1: The protective ratio of the antidotal formulas containing the experimentally tested imidazolium oximes as AChE reactivators

Table 8: The correlation between administered dose of acetylcholinesterase reactivator and the pharmacodynamic effect

Study group.	Reactivator dose used in the antidotal formula (mg)	AChE Mmol/ml	Correlation coeficicient
4	61,94	1,65	0,9927
8	78,58	2,01	
10	100	2,53	
12	118,88	2,84	

Legend:

Study group 4: poisoned study group and 1methyl-quinuclidine 3-on iodide treated;

Study group 8: poisoned study group and 1,3-dimethyl-2-hidroxyethyl-imidazolyl iodide treated;

Study group 10: poisoned study group and obidoxime chloride treated;

Study group 12: poisoned study group and 3 oxim[3(2-hidroxyiminomethyl-1-imidazolyl)-2oxapropyl] quinuclidine dichloride treated;

From a medical standpoint, an organophosphoric nerve poisoning that caused inhibition of acetylcholinesterase survival limit was applied.

This intoxication was further antagonized with different formulas containing the synthesized imidazoliumquinuclidinium oximes and obidoxime as antidotes.

They showed mean values of acetylcholinesterase significantly different from the poisoned and untreated group. The studied imidasolium quinuclidinium oximes showed average values of acetylcholinesterase statistically significantly different between them, thus emphasizing that the doses used may cause significant variations in therapeutic effect.

Table 8 highlights the so-called "dose finding", the correct correlation between dose and pharmacodynamic effect. The correlation coefficient of 0.9927 demonstrates that doses of acetylcholinesterase reactivators used in the antidotal formulas are correct, being those that cause maximum pharmacodynamic effect.

CONCLUSION

- 3-oxime-[3-(2-hidroxyimino-methyl-1-imidazolyl-)-2-oxapropyl] quinuclidindichloride synthesized in the Medical Military Research Centre Chemistry Department has shown a better protective ratio and a more prolonged surviving time than obidoxime considered as reference.
- It has shown the best acetylcholinesterase reactivation of all the synthetised compounds and obidoxime
- The very good correlation dose-effect highlights that the correct dose of acetylcholinesterase reactivator was chosen in order to obtain the better pharmacodynamic effect.

- 3-oxime-[3-(2-hidroxyimino-methyl-1-imidazolyl-)-2-oxapropyl] quinuclidindichloride can be considered an efficient antidote in neuroparalytic organophosphorous hazards.
- 3-oxime-[3-(2-hidroxyimino-methyl-1-imidazolyl-)-2-oxapropyl] quinuclidindichloride can be a cheaper and better option for replacing obidoxime in the antidotal formula active in nerve agent poisoning.
- Thus one can conclude that the result of the experimental study is consistent with the proposed object.

Dosimeters: measuring occupational UV exposure's involvement in skin cancer development

Adrian I. Lungu[4], Alexandra I. Butacu[1,4], Ionela Manole[3,4], Alina Suru[3,4], George S. Ţiplica[1,4], Carmen M. Sălăvăstru[2,4]

Abstract: *Introduction: Solar exposure is a major causative factor for multiple skin pathologies. Even though UV radiation is the most important factor implicated in skin cancer pathogenesis, still, few European countries recognize UV occupational-induced skin cancer as an occupational disease, Romania not being part of this category. The objectives of this study were to evaluate the UV exposure doses in agriculture and construction workers and to establish efficient protective measures.*

Materials and methods: In our Department, a prospective, observational, analytical study was conducted, including six outdoor workers (in construction and agriculture), over a period of three summer months (July, August, September). Subjects were asked to wear personal dosimeters and the following parameters were analyzed: profession, duration of exposure, UV exposure doses, skin aspect, preexisting preventive measures.

Results: The wearing of dosimeters was well tolerated by all subjects, without any interference with daily professional activities. Daily UV radiation doses ranged from 1.79 SED (tractor driver) to 19 SED (agriculture worker). Maximum UVR doses were recorded between 10:00 am and 4 pm. Clinical examination was made after measurements, with no detectable skin changes.

Conclusion: Even though workers in agriculture and construction in Romania are exposed to significant UV doses, with 40% more than the general population, these professions are not recognized as high-risk professions for developing skin tumors. More prospective and retrospective studies are necessary for more significant statistical results and for demonstrating the necessity of introducing primary, secondary and tertiary preventive measures.

Keywords: *ultraviolet radiation, occupational exposure, skin cancer*

INTRODUCTION

Solar exposure is a major causative factor for multiple skin pathologies. Most frequently it is the case of cutaneous tumors, both precancerous and malignant lesions (actinic keratoses, basal cell carcinomas, squamous cell carcinomas and melanomas). [1]

There are numerous professions that imply working

outdoors, from which we concentrated our study on agriculture and construction workers. Occupational ultraviolet (UV) exposure can be measured with UV dosimeters.

Personal UV dosimeters are electronic devices that are able to record data that permits analysis of UV exposure dose on working days. Modern dosimeters are small in size, therefore easy to wear at the workplace, permitting personal UV measurements. Even more so, multiple dosimeters can be used, recording data from different parts of the body. They are relatively new devices used more and more frequently in UV exposure-related studies. [2-5]

Ultraviolet radiations represent segments of the electromagnetic specter and are classified in UVC (100-290 nm), UVB (290-320 nm) and UVA (320-400 nm).

UV radiation is very important in dermatological practice, being able to determine both exacerbations and remissions of different skin disorders and of course playing a major role in skin cancer development. [6]

Even though UV radiation is the most important factor implicated in skin cancer pathogenesis and World Health Organization introduced UV radiation on the carcinogens agents list of group I, still, few European countries recognize UV occupational-induced skin cancer as an occupational disease, Romania not being part of this category. [7]

The lack of studies in this area in Romania suggests the fact that more analysis should be made for a better understanding of this aspect in our country.

Objectives: to evaluate UV exposure doses in agriculture and construction workers and to establish efficient prevention and protection measures.

MATERIALS AND METHODS

In our Department, a prospective, observational, analytical study was conducted, including six outdoor workers (in construction and agriculture), over a period of three summer months (July, August, September).

Subjects were selected based on their profession. Our study took place in Bordusani, Ialomita, Romania, with the geographical coordinates 44°28′21″N 27°53′59″E for the agriculture outdoor workers and in Bucharest, Romania, with the geographical coordinates 44°25′57″N 26°06′1 for the construction workers.

Subjects were asked to record in personal diaries information regarding: profession, location, date, start time and end time of their schedule, lunch breaks and weather conditions.

The following parameters were analyzed: profession, duration of exposure, UV exposure doses, skin aspect, preexisting preventive measures.

For the agriculture workers, we've selected irrigation system manufacturer, tractor driver and beans manufactures and for the construction site we've selected road workers.

Subjects were asked to wear personal dosimeters for several working days. Sun exposed areas involved the face, neck, forearms and dorsum of hands, the rest of the areas were covered by equipment.

Clinical examination was performed before and after measurements to detect any skin changes.

The personal dosimeter used in this study was X-2012-10 Personal UV Irradiance Dosimeter from Gigahertz-Optik and a "Velcro" fastening system was used to attach it on the subject's forearm.

Data was processed using Microsoft Office Excel 2013.

RESULTS

The wearing of dosimeters was well tolerated by all subjects, without any interference with daily professional activities.

Daily UV radiation doses ranged from 1.79 SED (tractor driver) to 19 SED (agriculture worker).

Maximum UVR doses were recorded between 10:00 am and 4 pm. Apart from standard equipment, no protective measures were applied.

Clinical examination was made after measurements, with no detectable skin changes.

DISCUSSION

Sunlight is composed of a continuous spectrum of electromagnetic radiation divided into three major groups: ultraviolet, visible and infrared. [8] Ultraviolet radiation is a major causative factor in skin cancer development. [9]

Even though UVA has less energy than UVB and penetrates deeper, into the dermis, UVB radiation is most implicated in carcinogenesis. UVA is responsible for carcinogenesis through immunosuppression: it determines production of reactive oxygen species that cause damage in the deoxyribonucleic acid, therefore gene mutations and damage in the epidermal keratinocytes and dermal connective tissue.

Examples of gene mutations include PTCH and p53 tumor suppression gene in basal cell carcinomas, activated mitogenic ras pathway and p53 in squamous cell carcinomas and ras pathway, inactive p16 and p53 in melanomas. [10]

Also, the duration and intensity of UV exposure are factors implicated in skin cancer development. For example, cumulative, long-term UV exposure is related to chronic actinic skin damage, therefore implicated in the appearance of actinic keratoses and squamous cell carcinomas, since intermittent, high intensity UV exposure especially at young ages would most likely cause basal cell carcinomas and melanomas. [11]

For measuring UV exposure doses on an outdoor worker, irradiance should be determined - the flux of radiant energy per unit (W/m2). But this applies only for one moment in time, so for a larger period (e.g. one working day) the term "exposure dose" (J/m2) is used. [12] For this, a standardized unit – SED – Standard Erythema Dose is applied, where 1 SED is equivalent with 100J/m2. [13]

The annual exposure dose for the general population in Germany is 130 SED. [14] Considering our results, with a daily UV exposure dose of 19 SED (15% daily of the annual exposure dose), we have to acknowledge the fact that both agriculture and construction professions in Romania are professions with high-risk of developing solar exposure related pathologies.

Even more so, by German standards, if the outdoor worker was exposed to a cumulative UVR dose with 40% higher than the general population, than the nonmelanoma skin cancer is considered to be of "occupational origin". [14]

Therefore these professions should be placed in the occupational skin diseases category.

It is very important to take into consideration that different parts of the body absorb different UV doses depending on body geometry, therefore involve different risks. Multiple personal dosimeters should be used, calculating UV doses on different body sites. [16]

Horizontal body locations seem to receive 2x - 2,5x more UV that the vertical ones. [17]

Also, UV exposure dose depends on the reflection of UV radiation on surrounding structures. For example, UV reflection for construction workers surrounded by metallic structures is different to that of fishermen that are surrounded by water. This is a significant additional benefit of personal dosimeters, being able to record UV doses from different parts of the body and not taking into consideration only the direct, vertical radiation.

For example, even if an outdoor worker has correct equipment, with a broad-brimmed hat, UV reflection from surrounding structures could still reach him. Therefore additional protective measures should be implemented, such as protective sun creams. Also, personal dosimeters, being able to measure UV radiation received by the subject, these measurements could be compared with those stated by meteorological departments. [18]

Even more so, occupational exposure to UV radiation can determine specific features of the tumors involved. For example, basal cell carcinoma appears more frequently in the "mask area" of the face in occupational exposed workers and also histopathologically appears to be more aggressive in evolution. [19]

All of this important features reinforce the necessity of implementing strict preventive and protective measures for outdoor workers, including protective sun creams (SPF 30 or more), special sun protective

equipment (long pants and long sleeves, broad-brimmed hats or helmets, sunglasses), multiple breaks in indoor areas and rotating shifts. [15] Also, considering the fact that the maximum UVR dose was detected between 10 am and 4 pm, outdoor workers should avoid working outside in this timeframe.

Even if by the end of our study no pathological skin changes were expected, we have to keep in mind that most UV skin related pathologies depend on a cumulative UVR dose with long term exposure. More interventional and observational studies are necessary for a better understanding of UVR effects on outdoor workers in Romania.

CONCLUSION

Even though workers in agriculture and construction in Romania are exposed to significant UV doses, with 40% more than the general population, these professions are not recognized as high-risk professions for developing nonmelanoma skin cancer or melanomas. More prospective and retrospective studies are necessary for more significant statistical results and for demonstrating the necessity of introducing primary, secondary and tertiary preventive measures.

Artificial Intelligence in cardiovascular medical imaging

Silviu Stanciu[1], Irina A. Tache[2], Magdalena Gurzun[1], Alexandru Sorici[2], Alexandru Croitoru[3], Dragos Cuzino[3], Diana L. Tudor[3], Sorin Lazar[4]

Abstract: *Artificial Intelligence (AI) has become an important tool for computer-aided diagnosis of medical imaging. This review aims to provide an overview for clinicians, explaining the relevant aspects of artificial intelligence and machine learning (ML) and presenting up-to-date applications of AI and ML techniques to medical imaging methods such as angiography, magnetic resonance, and echocardiography.*

For each imaging method, we present the acquisition process, the types of diagnostic test interpretation, and the challenges related to them, as well as how AI/ML techniques, have improved the process of decision making.

A summary of selected works applying AI/ML techniques to medical imaging is organized into a table, which highlights the scope of the study, the dataset used, the details of each approach as well as the measured results, including objectives and criteria. The overall benefits of AI in medical imaging are extracted based on the diverse applications and high evaluation scores. In the end, cardiologists should have an advanced understanding of using AI to integrate clinical data and making the final decision in diagnosis.

Keywords: *machine learning, cardiology, angiography, echography*

INTRODUCTION

The application of AI algorithms to a data set has the usual initial steps of developing the algorithm's ability to "learn" based on the training data and to apply the knowledge gained in making predictions. The “learning phase” of an algorithm consists of an incremental optimization of the model parameters with which it is configured, so that performance on a given training objective (e.g. classification of the most likely diagnosis, regression of numerical value of a health parameter) increases.

Machine Learning is a methodology used to recognize such patterns; the applicability of this can be extended very well in the context of medical imaging. Usually, this technique starts with the use of an ML-based system that determines those characteristics of the images that are considered to be important in making the prediction or diagnosis. As a result, the system identifies the best combination of these characteristics for the image classification and computes statistical data for the different regions identified.

The last decade demonstrates the huge potential of machine learning techniques in many domains along with the development of the graphical processing units (CPU/GPU),

[1] Carol Davila University Central Emergency Military Hospital Bucharest, Romania
[2] Faculty of Automatic Control and Computers,“Politehnica” University of Bucharest, Romania
[3] “Carol Davila” University of Medicine and Pharmacy, Bucharest, Romania
[4] University of Illinois Chicago, USA

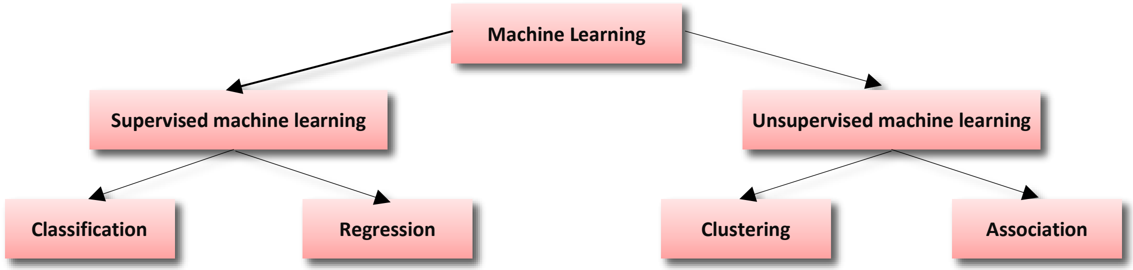
the availability of big data, and the growth of the learning algorithm efficiency [1].

Figure 1 shows the principal categorization of ML algorithms according to their main functionality. One can distinguish between Supervised Machine Learning (i.e. having an expert provide the so-called ground truth - the correct class or value - for each example in a dataset) and Unsupervised Machine Learning, where the objective is to find interesting patterns and frequent associations between examples in a dataset, without any human supervision (e.g. finding an automatic grouping of diseases by the similarity of symptoms).

Medical imaging applications mostly belong to the supervised ML category, because the correct interpretation (e.g. diagnosis, the classification of severity of a disease) of the result is provided by the medical experts who have analyzed it.

In the past decades, there was substantial growth in the healthcare applications one example is the deep learning algorithm that proved to have an outstanding accuracy in diabetic retinopathy identification [2].

Figure 1: Grouping the different types of machine learning algorithms according to the type of learning [3]



Yang et al [4] demonstrated the importance of AI about big data and parallel programming in medicine, especially in the field of cardiac imaging.

These last decades have also demonstrated the importance of medical imaging in the detection, diagnosis, and treatment of various conditions. In clinical applications, medical imaging is largely performed by a group of experts, such as cardiologists, radiologists, endocrinologists, and so on [5]. In this regard, the computer-assisted analysis enables a better interpretation of the medical image database available. Regarding the decoding of the parameters highlighted by the medical images, it is worth noticing the recent advances in deep learning techniques, which represent a considerable leap in the identification, classification, and quantification of medical conditions and/or health parameters based on input from different medical imaging techniques [6].

ARTIFICIAL INTELLIGENCE IN ECHOCARDIOGRAPHY

In the world of multimodal imaging in cardiology, echocardiography remains crucial for the diagnosis and management of patients with cardiovascular disease [7]. The advantages of the ultrasound of the heart compared to other imaging tools are low price, portability, the possibility of being repeated, short examination time, and the fact that the administration of contrast medium is unnecessary. However, errors in echocardiography quantification and conflict in the interpretation of echo images are frequent in everyday clinical practice.

Although it remains the main imagining modality used in cardiology, echocardiography has several shortcomings that can be improved. The echo machines have developed intensively during the last year (leading to accurate 2D and Doppler imaging and new technologies like tissue Doppler, speckle tracking, or 3D echocardiography). However, one of the main limitations of this method is high operator dependence. The learning curve in echocardiography is very steep and the knowledge, the experience, and sometimes even the mood of the echocardiographer are very important for the exam interpretation. For example, left ventricle ejection fraction is a crucial parameter for patient management but has a high inter- and intraobserver variability. Therefore, the result given by one observer can be different compared to another one or, even more, the same observer can give different interpretations when the reading is repeated. The purpose of AI is to overcome these issues.

Another important role of AI in this field is to solve the problem of a mismatch between the high number of echocardiography required in clinical practice and the number of cardiologists/echocardiographers available to interpret the studies. Moreover, a large volume of already acquired data is under-utilized during a routine echocardiogram and AI offers the possibility to interpret multiple datasets in a very short time [8].

The purpose of artificial intelligence in echocardiography is to detect the disease based on some specific echocardiographic criteria [9, 10]. AI can be used in the image-acquisition process as well and helps people with limited echocardiography training to obtain standard views by anatomic guidance.

Although the implication of AI in echocardiography is still less important compared to other imaging modalities, there are many examples of applications already being used.

Software algorithms are capable of correct identification of the ultrasound modality (2D, pulse wave Doppler or continuous wave Doppler) or the view (four-, two- or three-chamber view) [11]. Moreover, the identification of structures and even the quantification of some related parameters based on border detection are also possible. One of the first applications of AI in echocardiography was the assessment of left ventricular volumes and function initially based on 2D and subsequently on 3D [12]. Based on 3D echocardiography, the correct identification of the heart chamber borders offers results comparable to those measured by cardiac magnetic resonance (left ventricle volumes and function [13], right ventricle volumes, and function [14]. The new software can compute the chamber volumes not only at a maximum or minimum level but also dynamically through the cardiac cycle [15]. Some models for the automated diagnosis of regional wall motion abnormalities and myocardial infarction using deep learning algorithms are still developing [16].

AI is already aiding in valvular heart disease; there is automated software that offers the assessment of mitral [17] or aortic valve.

Some applications can already differentiate, with high sensitivity, between some pathological conditions that need an experienced human examination: left ventricular hypertrophy in athletic population vs. in hypertrophic cardiomyopathy [18], constrictive pericarditis vs. restrictive cardiomyopathy [19].

AI can change the way we read echocardiograms. Normally the interpretation of an echocardiogram is based on consecutive views analysis. For example, in aortic stenosis grading, the observer has to integrate information from multiple non-consecutive views (annulus diameter from the parasternal long axis, continuous wave and pulse wave Doppler data from apical 5 chamber or right parasternal). AI allows the classification of these images and the analysis of the ones related to aortic stenosis grading although they have not been acquired consecutively. Therefore, in the future, the reading of an echocardiogram will be based on the chamber or valve analysis in multiple views and not on the interpretation of consecutively acquired views.

A very important aspect is that using artificial intelligence in echocardiography can modify our understanding regarding the echocardiographic data. Our knowledge of echo interpretation is based on clinical trials that have included a target population. However, this population may not always be representative of the entire population. The large amount of data obtained by including artificial intelligence and machine learning in echocardiography can change our classifications, cut-offs, and interpretation of these data. For example, a recent study based on the NEDA registry (Australian New Zealand Clinical Trials registry) showed that patients with moderate aortic stenosis have similarly high rates of mortality compared to patients with severe aortic stenosis and, likely, we'll need to reevaluate our current data regarding the indications for intervention in aortic stenosis [20].

Therefore, in echocardiography, AI offers the possibility to interpret data from the real world and not from selected patients included in clinical trials and probably a better understanding of the diseases.

Recently, machine learning and deep learning have become the main direction of development in echocardiography, which is proved by the number of publications in PubMed [21]. The possible impact of artificial intelligence on echocardiography is impressive but for now, the human mind is still far too complex compared to AI [22].

Although we all dream of an automated program for echocardiogram interpretation, there is still a long journey ahead. Thus, cardiologists should have advanced knowledge and the capability to use artificial intelligence as extended intelligence.

ARTIFICIAL INTELLIGENCE IN CARDIAC MAGNETIC RESONANCE IMAGING

There is a concern among radiologists and medical students that AI will replace the radiologist. This is not likely to be the natural evolution, but radiologists who use artificial intelligence will replace those who do not or do not think they can use it.

The modern principles of medical imaging are based on the most efficient use of the techniques that bring the maximum amount of information in the shortest time possible, starting from the moment of clinical suspicion. This aspect makes it necessary for the clinician to know the value and the limits of each type of sectional imaging exploration, to optimize the indications of the examinations. Cardiac MRI has a very wide range of clinical applications and has been included in the guidelines for the assessment of congenital heart disease, heart tumors, pericardial disease, cardiac ventricular dysplasia, or myocardial ischemia - hibernating myocardium [23]. Other indications such as the evaluation of myocardial perfusion, ventricular or valvular function can be accurately evaluated by MRI, but compete with other imaging modalities, such as single-photon emission computed tomography (SPECT) and echocardiography, more commonly used in outpatient settings.

The major advantages of MRI are the absence of ionizing radiation and the very strong contrast and temporal resolutions (as opposed to CT, where the spatial resolution is very high [27]. Cardiac MRI provides a wealth of morphological and functional information about the heart. In some practices, the evaluation of the heart MRI requires a long global time, so the tendency is to standardize and reduce the time required for the exploration, but also for the analysis of the images obtained, by using the FAST MRI type techniques. To optimize these protocols for analyzing the data obtained from the scanning of the heart, AI techniques have been developed and used in clinical practice.

They are based on automatic machine learning techniques to enhance the ability to analyze images and data obtained by MRI scanning. The results are remarkable both in the optimization of scanning techniques and protocols, as well as in the analysis and integration of data and results. In an impressive achievement, the introduction of AI and the optimization through the machine learning algorithm can increase the speed of interpretation of the images obtained by cardiac MRI from an average of 13 minutes to about 4 seconds [24].

Cardiac MRI can establish the most appropriate plan for cardiac surgical planning, implantation of cardiac defibrillators, and assessment of cardiac toxicity in patients with oncological pathology. These decisions are based on the accuracy measurements made by MRI.

Multiple studies performed on significantly large numbers of patients have used the information to develop machine learning protocols [25]. These are based on neural network learning. For the time being, it is still necessary to validate the superiority of the efficient application of these AI-type protocols over the aspect of the presently considered examinations. At this moment, the cardiac MRI examinations intend to use a large database which, after a standardized examination and by using a minimum of subsequent maneuvers, the results will be offered in the form of measurements made automatically by the computer capable of filling an MRI result with multiple preformed fields. Also included in this result with preformed fields, the neural network algorithm also offers the diagnostic suspicions based on which differential diagnoses can be issued. The vision of those who work and create this advanced analysis and diagnostic software is to increase the speed of examination without sacrificing the accuracy and precision of interpretation.

The use of artificial intelligence is used to solve the following problems and challenges - the small number of radiologists, the long time required for each examination, the insufficient use of radiological equipment without corresponding efficiency [26].

Traditionally, CT and ultrasound are the most frequent techniques used for cardiac imaging examinations. However, MRI can occupy a very important place due to the very important contrast of tissue structures without ionizing radiation.

One of the major disadvantages of cardiac MRI is that the examination lasts for about an hour. For example, an existing software solution, called Heat Vista (available in the US), reduces the examination for suspected cardiac ischemia from 90 minutes to 15 minutes, and the solution is applied to existing equipment. The software recommends the protocol for about 10 seconds. All these technological advances also eliminate the need to examine through sequences with blocked breathing. This progress is achieved through sequences that recognize and detect artifacts and alert the technician if the sequence needs to be redone [28].

Another challenge is MRI examinations for patients with cardiac and vascular implants of various types of devices. It is necessary to adapt these protocols to the particular aspects of each patient and this aspect can be efficiently optimized by AI protocols depending on the type of implant and the manufacturer that produced them. Considering all the above, cardiac imaging and especially cardiac MRI will benefit from the integration of various AI solutions.

ARTIFICIAL INTELLIGENCE IN CARDIAC ANGIOGRAPHY

X-ray angiography is a medical imaging technique dedicated to the diagnosis and even treatment of vascular diseases. An angiography is obtained using an X-ray source and a detector located on both ends of a C-arm gantry. The imaging apparatus provides temporal images series for several seconds.

Table 1: Artificial Intelligence in cardiovascular medical imaging

Imaging Technique	**Scope**	**Dataset**	**Approach Details**	**Measured Results**
Cardiac MRI	Ventricle Segmentation [29]; Estimating Left Ventricle and Right Ventricle functioning	Cardiac MRI datasets, MICCAI 2012 RV segmentation challenge; 48 patients (16 training, 32 test)	Region of Interest (ROI) extraction using 960 cardiac MRI images with manually labeled RV and LV bounding boxes of size 150 x 150 px. Objective: contour overlap of segmented RV with ground truth Criteria: DM, HD, R, ME for EDV, ESV, and EF.
	Heart chamber segmentation [30]; Analyzing abnormality of wall motions	Cardiac MRI datasets, MICCAI 2012 RV segmentation challenge	Heart chamber ROI extraction using a deep learning approach for semantic segmentation. The segmentation approach was initialized with input from a prior edge detection algorithm.	Objective: contour overlap of segmented RV with ground truth Criteria: DM, HD, R, ME for EDV, ESV and EF.
Echocardiography	Regression task: left ventricular volume and ejection fraction computation; Decision making in valvular heart disease, heart failure and post-infarct care [31]	255 usable 2-dimensional echocardiography (2DE) studies	Local Ejection Fraction (EF) estimation. Comparative evaluation of automated EF measurements against manual inspection.	Objective: automated EF estimation Criteria: Intraclass correlation coefficients Bland-Altman analyses
	Regression task: left ventricular volume and Ejection Fraction estimation; [32]	218 patients including 165 with abnormal left ventricular (LV) function. 10,000 apical 4- and 2-chamber view images, from patients with cardiomyopathies, wall motion abnormalities, and dyssynchrony. Cardiac MRI for 21 patients	Identification of the Left Ventricle cavity. Manual tracing of the endocardial border. Left Ventricle volume estimation using modified Simpson's rule for Ejection Fraction computation.	Objective: automated EF estimation Criteria: 2-tailed Student t-test Bland-Altman analysis
Myocardial Perfusion Imaging (MPI) + Coronary angiography	Automatically predicting obstructive disease likelihood from myocardial perfusion imaging (MPI) [33]	1,638 patients without known coronary artery disease, undergoing stress 9mTc-sestamibi or tetrofosmin MPI in 9 different sites Coronary angiography performed within 6 months of MPI	Semantic segmentation of myocardium using a neural network method trained on raw and quantitative polar maps. Input for the network obtained using manual annotation of images obtained from nuclear cardiology software tools.	Objectives: obstructive disease prediction Criteria: area under the receiver-operating characteristic curve (AUC), sensitivity (SS)
SPECT+ computed tomography angiography	Estimating the likelihood of abnormality of coronary arteries in patients with ischemia [34]	1001 patients Coronary angiography within 60 days of myocardial perfusion SPECT for 59 patients with stable coronary artery disease	Semantic segmentation of artery zones with perfusion disorders. Use of segmentation to extract features such as shape, extent, location, count, perfusion homogeneity, regional motion, wall thickening, and sex	Objectives: obstructive disease prediction Criteria: SS, specificity, accuracy, AUC

DM – Dice metric, HD – Hausdorff distance, R – correlation coefficient, ME for EDV – mean errors for end-diastole volumes, ESV – end-systole volumes, EF – ejection fraction, MRI – magnetic resonance imaging

There are three types of angiograms: (i) monoplane angiography, which is the most common method and utilizes the single view principle, (ii) biplane angiography, which uses two C-arm systems for simultaneous acquiring of two different projections, and finally, (iii) rotational angiography, which can give the most accurate three-dimensional scenes by making a complete rotation around the patient.

In [33], the angiography and myocardial perfusion imaging are acquired from the same patient and used as training data on an artificial neural network (ANN) for an automatic prediction of obstructive disease. In [34], the coronary angiography is acquired within 60 days of myocardial perfusion SPECT for patients with stable coronary artery disease from a Japanese hospital. The purpose of ANN was to detect the coronary arteries responsible for the patients' cardiac ischemia. The algorithm accuracy to diagnose the culprit artery was similar to that of a medical expert.

Opportunities for AI applications at the peri-intervention stage are presented in [35] where diverse clinical investigations such as angiography, EKG, biomarkers are reunited for diagnosing STEMI patients. Some applications of machine learning techniques in angiography and other cardiac imaging methods can be found in Table 1.

CONCLUSIONS

The next challenge will be moving from focusing on technique and image analysis to tasks dedicated to physicians in the context of automation of other tasks. This may increase the time efficiency of the medical procedures, job satisfaction, better communication between patient-physician, and improvement of healthcare equality. AI-based solutions will contribute to fighting modern days' challenges, such as the decreasing number of skilled radiologists, leak of medical equipment used, and time-consuming diagnoses.

The final decision after integrating clinical data belongs to cardiologists. The role of artificial intelligence is not to replace humans but to make their work more accurate, fast, and efficient.

A simple approach for risk stratification in the plan of exercise in older adults

Mehmet I. Naharci[1], Oznur Buyukturan[2], Ilker Tasci[1,3]

Keywords: *aged; exercise; risk*

Letter to the Editor

The benefits of physical activity (PA) in decreasing morbidity and increasing life span have been proven at all ages, even in later life [1]. In addition, PA not only improves the quality of life but also contributes to maintenance of social and psychological well-being [2].

There are a lot of specific PA programs for adults aged over 65 years, with various recommendations and implementations. However, adherence and persistence in PA are generally not at desired levels in these individuals [3]. While numerous causes can decrease the compliance in PA, a set recommendations specific to person's condition and needs can successfully be used to individualize the exercise plan in older adults. Comorbid conditions and functional impairment can reduce engagement in PA. Therefore, these should be reviewed in the first step of a systematic approach by the physicians, especially in the primary care setting.

In order to improve the efficacy of PA plan offered to an older adult, we intended to test a novel approach in small sample of community dwelling elderly. The proposed tool classifies the subjects in three categories based on a geriatric evaluation that includes review of chronic diseases and 12-month fall history, assessment of cognitive status [assessed by Mini-Mental State Examination (MMSE), range 0-30], and screening for the functional status (assessed by KATZ index, range 0-6) [4, 5].

1. Low-risk individuals: Those with no or a single chronic disease, no cognitive impairment (MMSE score ≥ 28), no functional impairment (KATZ score ≥ 5), and no history of falls in past 12 months.

2. Medium-risk individuals: Those with two or more chronic diseases, mild cognitive impairments (MMSE score ≥ 24 and ≤ 27), mild functional disabilities (e.g., using a cane or walker) (KATZ index score 3 or 4) or positive history of falls without injury in past 12 months.

3. High-risk individuals: Those with two or more chronic diseases, significant cognitive impairment (MMSE score ≤ 23), advanced functional disability (KATZ index score ≤ 2), or positive history of falls with injury in past 12 months.

Table 1 suggests some exercise recommendations for the risk groups [6].

Encouraging older adults to participate in PA is an important issue at the primary care level. There are still problems to

Assessment of complications and outcomes of mechanical bowel obstruction in a military hospital

Soleyman Heydari[1], Sardollah Mahmoodi[1], Hamid R. Javadzadeh[1], Hassan Goodarzi[1]

Abstract: *Aims: Mechanical bowel obstruction is a frequent surgical emergency and a frequently confronted burden in abdominal operation. This study aimed to find out the model of mechanical bowel obstruction in the Iranian population.*

Methods and materials: In this study, all patients with clinical and radiological evidence of mechanical bowel obstruction that admitted to the Department of Surgery of Baqiyatallah Hospital with a diagnosis of mechanical bowel obstruction from January 2012 to December 2015 were included. The age, gender, symptoms operative details, postoperative complications, outcome, and mortality, were recorded.

Results: 193 patients with mechanical bowel obstruction were admitted in our study. Regarding the clinical presentation of the patients, the absence of passage of flatus and/or feces with abdominal pain (65.8%) were the most common presenting symptoms. Adhesions, colonic volvulus, hernias, different types of colorectal cancer were the most frequent causes of obstruction (54.9%, 15.54%, 7.2%, and 9.8%, respectively). Twenty-one patients died, resulting in a mortality rate of 10.9%. In the 19 patients with colorectal cancer, 7 (31.6%) patients have died and cause of death in all them related to cancer disease.

Conclusion: The results showed that the most common mechanisms of intestinal obstruction were adhesions, volvulus, cancers, and hernias, respectively, and the most common risk factors were appendectomy history, herniation surgery history, and cholecystectomy history, respectively. About 21 patients (10.8%) underwent obstruction surgery with a diagnosis of malignancy, which was confirmed in 19 cases of tumor pathology, of which about one third had recurrence within 3 years.

Keywords: *mechanical bowel obstruction, adhesions, colorectal cancer*

INTRODUCTION

Mechanical bowel obstruction is a frequent surgical emergency and a frequently confronted burden in abdominal operation [1-3]. Intestinal obstruction relates to extremely severe circumstances, demanding a fast and accurate diagnosis as well as critical, rational, and efficient treatment [4].

The diagnosis of mechanical bowel obstruction is not always simple, and an implication of operation requires a vast indication of suspicion [5, 6]. Comprehensive past and precise clinical exams are important to obtain a practical diagnosis and preparation therapy [7]. There are several cardinal characteristics, i.e. colic, distension, vomiting, and constipation, but the influence of each of these is affected by the position and kind of obstruction [5-9]. The administration needs early diagnosis and therapy with meticulous fluid, electrolyte balance, and timely operational intervention [10]. The complications can be decreased by

[1] Trauma Research Center, Baqiyatallah University of Medical Sciences, Tehran, Iran

early diagnosis and immediate surgical intervention [11].

Emergency surgery for malignant bowel obstruction is correlated with a mortality incidence of up to 30 percent [12]. It also results in considerable morbidity with prolonged hospital stay, delay at the beginning of chemotherapy and many stoma organizations, with a disorder of quality of life [12-14].

Also, malignant bowel obstruction has a major affected on health costs given that these cases are hospitalized and may need multiple mediations [13]. Medical administration has lower short-term mortality but may be correlated with low resolve or recurrence of the obstruction [14]. Because of the enormous problem of MBO in cases with cancer and the meaningful discrepancies in the morbidity of surgical versus medical treatments, it is necessary to characterize the predictors of survival and the impact of therapy modality on case results [15]. However, MBO may be due to the primary tumor, metastatic disease, or past surgical intervention leading to adhesions or an internal hernia [16, 17]. Albeit, many studies showed that MBO in the setting of colon cancer, the actual incidence, and the results remain unknown [9, 12-16].

In a study showed that 10-50% of patients with advanced cancer stage would develop MBO during their illness and experience from intractable abdominal pain, vomiting, which result in a decreased quality of life, mental and emotional problems [18]. Various therapies, including operation, palliative radiotherapy, chemotherapy and total parenteral nutrition formulas, may be used to reduce the symptoms in MBO patients; however, there is currently no agreement about the optimal treatment approach and no substantial evidence supporting the effectiveness of any treatment in enhancing the quality of life and prolonging survival [16-18]. Varying the pattern of the disease from time to time needs periodic studies to assess the etiological factors and behavior of the disease [12-18]. Also, as well as regional differences in the pattern of bowel obstruction and changes in the illness pattern over the years, are well documented in the previous studies [18]. This study aimed to find out the model of mechanical bowel obstruction in the Iranian population.

METHODS AND MATERIALS

In this study, all patients with clinical and radiological evidence of mechanical bowel obstruction that admitted to the Department of Surgery of Baqiyatallah Hospital with a diagnosis of mechanical bowel obstruction from January 2012 to December 2015 were included. The enrollment of the patients in the study was approved by the ethics committee of the Baqiyatallah University of Medical Sciences and written informed consent was obtained from all patients. Patients with paralytic ileus were excluded from our study.

The age, gender, symptoms operative aspects, post-operative complications, result, and death were recorded. Following clinical investigations, every six hours with the same attending surgical unit were conducted in all cases to assess the patients' symptoms. All cases had been operated on by the authors in the general surgery departments of the Baqiyatallah hospitals.

The diagnosis was based on clinical judgments, history, and supported by ultrasonography and radiological studies (plain x-rays) in all cases. The final diagnosis was presented at exploratory laparotomy, which was endeavored following thorough first evaluation, examinations, and resuscitation. The operation was determined as required in those patients where the operation was conducted in thirty-six hours.

Chi-square test and Fisher's exact test was utilized for the relationship between qualitative variables. The non-parametric Mann-Whitney test made a comparison among the groups. The Kolmogorov–Smirnov test was used for the normality of the data. The data was used by SPSS 20 software. The significance level for the tests was considered less than 0.05.

RESULTS

193 consecutive patients with mechanical bowel obstruction were included. The average age was 58.1 ± 19.0 years while women comprised 32.64% of the group. The most of the patients (60.1%) presented in above 59 years old.

Regarding the clinical presentation of the patients, the absence of passage of flatus and/or feces with abdominal pain (65.8%) were the most common presenting symptoms, only abdominal pain (27.5%) was the second frequent physical finding on clinical examination abdominal.

Regarding the types of previous operations, 35 patients (23.33%) had undergone an appendectomy, 27 (18.0%) hernia procedures, 24 (16.0%) had a cholecystectomy, and 86 (43.3%) had other surgical procedures.

Adhesions, colonic volvulus, hernias, different types of colorectal cancer were the most frequent causes of obstruction (54.9%, 15.54%, 7.2%, and 9.8%, respectively). There was no significant difference in the cause of obstruction regarding gender and age levels. An evaluation of 193 cases of mechanical bowel obstruction from the standpoint of etiology, age, and sex distribution, is presented.

Types of colorectal cancer were overrepresented accounting for 8 (42.1%) with obstruction due to sigmoid cancer, whereas six (31.6%) patients had a colon cancer, 3 (15.8%) had a cecum cancer, and one (5.2%) had a rectum cancer.

Regarding the clinical presentation of the patients and cause of obstruction, Adhesions and abdominal pain (56.08%) with were the most common presenting symptoms and cause of obstruction. The absence of passage of flatus and/or feces and Adhesions (33.9%) were the second frequent presenting symptoms and cause of obstruction.

There was a significant association between the cause of obstruction and history of surgery (P<0.001).

109 patients (56.4%) of the total study group were safely and more efficiently treated.

Eighty-four cases of the 193 patients sustained complications; 28 (33.3%) suffered from recurrence adhesion along with obstruction, 15 (17.9%) had abdominal pain, 15 (17.9%) had constipation. In the 19 patients with colorectal cancer, six (31.6%) patients had a recurrence.

Twenty-one patients expired, following in a death rate of 10.9%. In the 19 patients with colorectal cancer, 7 (31.6%) patients have died and cause of death in all them related to cancer disease.

DISCUSSIONS

In the past, the most common cause of intestinal obstruction was a strangulated hernia, but today, due to the higher prevalence of surgery than in the past, the most common cause of intestinal obstruction (75-80% of cases) is adhesions due to previous surgeries [7, 9, 11, 12]. These patients present with clinical signs of obstruction including colic abdominal pain, abdominal distension, and nausea and vomiting, and constipation. The complete obstruction causes intestinal dilation with an accumulation of water and gas. Radiological signs are visible 3-5 hours before obstruction [11-13]. In the present study, the most common postoperative diagnoses were adhesions in 106 patients (54.9%), volvulus in 30 cases (15.5%), colorectal cancers in 19 patients (9.8%) and hernias in 14 patients (7.2%), respectively. While in the study of Saber, the diagnosis of the cause of obstruction was observed in most cases with sigmoid volvulus and inguinal hernia, each with 18% and the site of obstruction in the small intestine with 55%. The most common symptoms in the present study were abdominal pain, which was seen in more than 95% of cases, and the second most common symptom was lack of gas or stool, which was seen in more than 65% of cases. In the study of Markogiannakis et al., the most common symptoms were flatulence (90%) followed by bloating and abdominal pain (65.3%). Adhesion was observed in 64.8% of cases, incarcerated hernia in 14.8%, and colon cancer in 13.4% [3].

Füzün et al. (2005), which looked at the causes of mechanical intestinal obstruction, found that intestinal adhesions were the most common cause of obstruction with 44%, followed by hernias with 23.9% and volvulus with 12.7%. Colon carcinoma was 10.1% of the causes of intestinal obstruction [9]. Our study is consistent with the above study in terms of 4 common factors and only slightly different in order after the most common cause, which is adhesion in both studies. The prevalence of colorectal cancers is very close in the two studies.

Regarding the clinical presentation of our cases, the lack of passage of feces or/and flatus with abdominal pain were the many common presenting symptoms and abdominal pain was the second most prevalent physical conclusion on clinical research [12-14]. The results, even though some variations are marked, are in agreement with the studies. Especially, Cheadle et al. showed abdominal vomiting 82%, pain 92%, distention 59%, and abdominal tenderness 64% as the most frequent signs [19]. While abdominal distension, bilious vomiting, absolute constipation, and abdominal pain were the main signs and symptoms in another study. In research on 100 patients with adhesive small bowel obstruction and recognized that the most common symptoms were vomiting 77%, colicky abdominal pain 68%, and absence of passage of flatus and/or feces 52% while abdominal distension developed the most common clinical symptom with a rate of 56% [20]. In a study of patients with bowel obstruction due to large bowel volvulus, the most common symptom of sigmoid volvulus was distension 79% and the most common symptoms were pain 58% and obstipation 55%, while most patients with cecal volvulus presented with pain 89% [21]. Moreover, in a review study of patients with obstruction because of small and large bowel intussusception, abdominal pain, nausea, vomiting, and abdominal distension were the frequent symptoms and signs, respectively [22].

Adhesions, colonic volvulus, hernias, different types of colorectal cancer were the most common causes of obstruction [23]. These results were also mentioned in the current research.

Furthermore, adhesions were the most common etiology of obstruction in and the total study group. Several studies propose that adhesions are responsible for 32%-74% of bowel obstruction and are the leading cause of small intestinal obstruction representing 45%-80% of it [20-23]. The large majority of the cases with adhesive obstruction have experienced previous abdominal procedures [23]. In the present study, this was agreement with previous studies.

The model of mechanical intestinal obstruction shows a difference in various areas. The obstructed herniae were observed as the 3rd common condition in the current research, whereas it was the second common condition of the other research, which almost is comparable with the other investigations carried in the country [14-15]. As for the types of surgeries in our cases, appendectomies, and hernia surgeries, cholecystectomies were more prevalent. This results also in agreement with the literature [9, 16].

However, the proper administration of adhesive obstruction is still uncertain, a large portion of these cases, varying from 35% to 65% in some investigations, can reliably and efficiently be managed with operation administration as it was also noted in our cases [23, 24].

The growing performance of adhesions as a condition of acute intestinal obstruction requires a higher requirement for regular precautionary standards toward adhesion formation [25]. Some effective actions are now supported through elective abdominal surgery to reduce the increase of adhesions that might consequently produce intestinal obstruction [26].

In previous studies showed sigmoid cancer is the etiology of obstruction that cases with high intestinal obstruction with a percentage of 40%-90% [27]. A study by Baloch et al., of 252 patients with mechanical bowel obstruction, showed due to the regional epidemic, the most common cause of obstruction was abdominal tuberculosis, which was observed in 30% of cases, and unlike our study and most other studies, adhesion was the second most common cause of obstruction. Also, in this study, the hernia was observed in only 17.5% of patients [15].

In our research, complication and mortality percentage were almost small. In the previous studies, complication proportion varies from 6 to 47 percent while death ranges from 2 to 19 percent [25, 28]. In our study, there was the association between mortality rate and colorectal cancer disease.

CONCLUSION

The results showed that the most common mechanisms of intestinal obstruction were adhesions, volvulus, cancers, and hernias, respectively, and the most common risk factors were appendectomy history, herniation surgery history, and cholecystectomy history, respectively. About 21 patients (10.8%) underwent obstruction surgery with a diagnosis of malignancy, which was confirmed in 19 cases of tumor pathology, of which about one third had recurrence within 3 years.

Assessment of patient satisfaction with primary health care in a military setting: A cross-sectional study from Turkey

Alper Tunga Kokcu

Abstract: *Background and Aim: Information on patients' experiences with and evaluations of health care is considered an essential outcome indicator to assess the quality of health care. This study aims to evaluate patient satisfaction with primary health care in a military setting.*

Methods: This cross-sectional study was conducted at the primary health care center located in a military setting, in Ankara, Turkey. A total of 3080 military personnel who received primary care in the last 12 months formed the population of the study. Turkish version of the European task force on patient evaluations of general practice care (EUROPEP) questionnaire was administered to the participants.

Results: In the study, 2677 participants were reached with a response rate of 86.9%. The mean satisfaction rate (MSR) of clinical behaviour (69.3%) was higher than the MSR of the organization of care (58.4%). The MSR of the overall questionnaire was 67.1%. Significant differences were observed in the mean satisfaction scores of patients according to their descriptive characteristics including gender, age level, troop type, and the doctor providing the care.

Conclusions: This study highlights the low patient satisfaction levels, which may have resulted from the fact that the study population was young and relatively healthy, and that there was no possibility of choosing the general practitioner. The EUROPEP questionnaire, which is an internationally validated and standardized instrument, can also be used to improve primary health care in military settings.

Keywords: *doctor-patient relationship, military medicine, patient satisfaction, primary care, quality of care*

INTRODUCTION

The World Health Organisation's definition of quality of care is "the extent to which health care services provided to individuals and patient populations improve desired health outcomes. To achieve this, health care must be safe, effective, timely, efficient, equitable, and people-centered." [1]. There are various parameters or indicators to judge the quality of health care. The measurement of patient satisfaction is considered as an essential outcome indicator to evaluate health care quality. Questionnaires are the most widely used instruments to assess patient satisfaction [2,3]. Although there is a controversy about measuring patient satisfaction or patient experience of the quality of care, many authors hold that satisfaction is linked to patient expectations of ideal care and their real experience of care [4].

In 1997, it was stated by the Council of Europe that the continuous improvement of quality of care is a key priority for all member states. According to this decision, information on the needs, priorities, and experiences of patients at all levels of care provision had to be gathered through appropriate methods ensuring the active participation of patients [5]. A valid and easy-to-use instrument to gather information on patients' experiences with and evaluations of general practice care was developed by the European working party on quality in general practice in 1999. The European task force on patient evaluations of general practice care (EUROPEP) instrument was designed to assess the quality of general practice and to provide relevant feedback to general practitioners, patients, and health care policymakers at different levels [6]. The EUROPEP questionnaire, which is an internationally validated and standardized instrument for patients' evaluations on general practice care, has been used in many European countries, including Turkey.

The objective of this study was to evaluate patient satisfaction with primary health care in a military setting by using the EUROPEP questionnaire. The impact of the differences in patient characteristics on their satisfaction was also investigated. Besides, comparisons were made between this study and other studies, especially those conducted with the EUROPEP questionnaire.

METHODS

This cross-sectional study was conducted at the primary health care center (PHCC) located in Gendarmerie and Coast Guard Academy, in Ankara, Turkey. A total of 3080 military personnel who received care from the PHCC in the last 12 months formed the population of the study. Since the whole population was included in the study, a sample was not chosen. The data were collected between August and October 2018.

Using a five-point answering scale with the extremes labeled as 'poorest' and 'excellent,' the EUROPEP questionnaire is a multidimensional instrument comprising 23 questions on evaluations by patients of specific aspects of general practice care. The questionnaire has two dimensions: clinical behavior (items 1-16), and organization of care (items 17-23). Through this questionnaire, patients are asked to rate the quality of care that they have received in the last 12 months from the general practitioner that they usually visit [6]. In 2002, Akturk et al adopted the English version of EUROPEP questionnaire into Turkish and demonstrated that the Turkish version of EUROPEP questionnaire is a valid and reliable instrument that can be used for the Turkish population [7]. Three items of organization of care (making an appointment and contacting PHCC or doctor by phone) not applicable in this study were removed from the EUROPEP questionnaire. In the study, the remaining 20 items of the Turkish EUROPEP questionnaire (items 1-16: clinical behavior; items 17-20: organization of care) were administered to the participants. Descriptive characteristics of the participants were also obtained through the questionnaire.

Participants who scored the two most positive answering categories (good and excellent) were considered as satisfied patients. The rate of satisfied patients was used for the description of patients' views for each item. For the overall questionnaire and each dimension, the mean satisfaction rate (MSR) was used to assess patient satisfaction. Additionally, each item was scored on a five-point answering scale, ranging from one (poorest) to five (excellent). The mean satisfaction score (MSS) and the standard deviation of mean were used for each item. For the overall questionnaire and each dimension, MSS was used to assess patient satisfaction according to descriptive characteristics.

The internal consistency was assessed by using Cronbach's alpha. The data analysis was performed using the SPSS 22.0 software package. As the dataset was neither distributed normally nor was homogeneous, non-parametric statistical tests were used in the analysis. Mann-Whitney U test and Kruskal-Wallis test were used to determine whether there was any difference in the answers of patients according to their descriptive characteristics. If the Kruskal–Wallis test was found to be statistically significant, Dunn-Bonferroni test was performed for pairwise comparisons. A value of $p<0.05$ was accepted as statistically significant. The descriptive tables including numbers, rates, and means are presented and the results are discussed at the end of the paper.

The necessary administrative permission was obtained from the command of the military setting before the study. The ethical approval for this study was provided by the relevant University Human Research Ethics Committee on 4 July 2018 (No:3304). The completion of the questionnaire was voluntary and anonymous. Consent forms were obtained from the participants before the administration of the questionnaire.

RESULTS

In the study, 2677 participants were reached with a response rate of 86.9%. In subgroups according to the descriptive characteristics of the participants, response rates ranged from 81.2% to 92.3%. All of the participants were military personnel of four different troops and received care from

PHCC at least one time over the last 12 months. General practice care was given by two doctors working in PHCC. Most of the patients were unmarried (n=2251; 84.1%) and male (n=2472; 92.3%). The mean age of patients was 24.8±2.5 and ranged from 18 to 40 years. The descriptive characteristics of the patients are summarized in Table 1.

In the study, all items of the questionnaire were aggregated into two dimensions: clinical behavior (items 1-16) and organization of care (items 17-20). The Cronbach's alpha ranged between 0.975 for "clinical behavior," and 0.883 for "organization of care." For the overall 20 items of the Turkish EUROPEP questionnaire, the Cronbach's alpha was 0.974.

Table 1: Descriptive characteristics of the patients (n=2677)

Characteristics	n	(%)
Gender		
Male	2472	(92.3)
Female	205	(7.7)
Marital status		
Unmarried	2251	(84.1)
Married	426	(15.9)
Age level		
18-20	158	(5.9)
21-25	1408	(52.6)
>25	1111	(41.5)
Troop type*		
A	1997	(74.6)
B	347	(13.0)
C	176	(6.6)
D	157	(5.8)
Visit number		
1-2	1663	(62.1)
3-4	637	(23.8)
>4	377	(14.1)
Dr. providing the care*		
Dr-A	1436	(53.6)
Dr-B	1241	(46.4)

**Names of the troops and doctors were encoded because of confidentiality*

For each item, the MSS and the rate of patients who scored the two most positive answering categories (good and excellent) are presented in Table 2. The highest satisfaction rate and MSS were observed for "keeping your records and data confidential" (81.2%; 4.15±0.86), "thoroughness" (75.9%; 4.06±0.97), and "listening to you" (75.9%; 4.04±0.96). The lowest satisfaction rate and MSS were found for "waiting time in the waiting room" (47.2%; 3.30±1.25), and "the helpfulness of the staff (other than the doctor)" (56.5%; 3.56±1.16). MSR of clinical behavior (69.3%) was higher than MSR of organization of care (58.4%). The MSR of the overall questionnaire was 67.1%. While the MSS of clinical behavior was 3.89±0.85, the MSS of organization of care was 3.60±1.00. For the overall general practice, the MSS was 3.84±0.84.

It was observed that there were significant differences in the MSSs of patients according to their descriptive characteristics including gender, age level, troop type, and the doctor providing the care. The MSS of female patients was lower than the MSS of male patients ($p<0.05$). The MSS of patients in the 18-20 age group was higher than those in the other age groups ($p<0.05$).

Regarding the overall questionnaire and each dimension, the patients from troop-A had lower MSS, compared to the patients from troop-C and troop-D ($p<0.05$). Regarding the dimension of clinical behaviour, the patients from troop-A also had lower MSS, compared to the patients from troop-B ($p<0.05$). Patients consulting Dr-A reported more satisfaction regarding the organization of care and overall general practice than the patients consulting Dr-B ($p<0.05$). However, there were no differences among other descriptive characteristics of patients such as marital status and the number of visits. The detailed results of comparisons of MSSs concerning the descriptive characteristics are given in Table 3 and Table 4.

DISCUSSION

It can be said that patient satisfaction is related to the physicians' adherence to the four principles of biomedical ethics including autonomy, beneficence, non-maleficence, and justice. Physicians' adherence to the principles of biomedical ethics, especially of autonomy, can be evaluated by using the instruments for assessing patient satisfaction. Most of the time, patients are not aware of the quality of health care delivered to them. Therefore, valid and reliable instruments are used to evaluate patients' experiences of health care.

In this study, the EUROPEP questionnaire was used for the assessment of patient satisfaction with primary health care in a military setting for the first time. Having this study conducted with the EUROPEP instrument allows us to make direct comparisons between the results of this study and the results of previous studies conducted with the same instrument. Similar to other studies, the current study revealed very high values for Cronbach's alpha for the EUROPEP questionnaire and its two dimensions [8-10]. For the overall questionnaire and each item, this study reported low patient satisfaction levels. Significant differences were observed in the MSSs of patients according to their descriptive characteristics including gender, age level, troop type, and the doctor providing the care. On the other hand, no differences were determined among other descriptive characteristics of patients, such as marital status and the number of visits.

Consistent with the previous EUROPEP studies, the results of this study showed that the patients were more satisfied with "clinical behavior" compared to the "organization of care." [8,9,11-14]. Similar to other studies, the highest and lowest satisfaction rates were for the items ''keeping your records and data confidential'' (81.2%), and "waiting time in the waiting room" (47.2%) [8-10,12-14].

Table 2: Descriptive statistics for 20 items of the questionnaire (n=2677)

Questions	MSS (Mean±SD)*	Good or excellent response [n (%)]**	
Clinical behaviour			
1. Making you feel you had time during consultations	3.80±1.02	1768	(66.0)
2. Interest in your personal situation	3.85±0.99	1802	(67.3)
3. Making it easy for you to tell him or her about your problems	3.97±0.95	1953	(73.0)
4. Involving you in decisions about your medical care	3.82±0.99	1763	(65.9)
5. Listening to you	4.04±0.96	2032	(75.9)
6. Keeping your records and data confidential	4.15±0.86	2173	(81.2)
7. Quick relief of your symptoms	3.85±1.00	1809	(67.6)
8. Helping you to feel well so that you can perform your normal daily activities	3.89±0.97	1867	(69.7)
9. Thoroughness	4.06±0.97	2033	(75.9)
10. Physical examination of you	4.00±0.99	1942	(72.5)
11. Offering your services for preventing diseases	3.89±0.98	1823	(68.1)
12. Explaining the purpose of tests and treatments	3.80±1.05	1744	(65.1)
13. Telling you what you wanted to know about your symptoms and/or illness	3.87±1.01	1833	(68.5)
14. Helping you deal with emotional problems related to your health status	3.72±1.05	1646	(61.5)
15. Helping you understand the importance of following his or her advice	3.86±0.99	1810	(67.6)
16. Knowing what he or she had done or told you during contacts	3.75±1.06	1688	(63.1)
MSS and MSR (items 1-16)	3.89±0.85		(69.3)
Organization of care			
17. Preparing you for what to expect from a specialist or hospital care	3.83±1.05	1784	(66.6)
18. The helpfulness of the staff (other than the doctor)	3.56±1.16	1512	(56.5)
19. Waiting time in the waiting room	3.30±1.25	1264	(47.2)
20. Providing quick services for urgent health problems	3.71±1.17	1690	(63.1)
MSS and MSR (items 17-20)	3.60±1.00		(58.4)

MSS: Mean satisfaction score; MSR: Mean satisfaction rate; SD: Standard deviation.

* *Items were scored on a five-point answering scale, ranging from 1 (poorest) to 5 (excellent).*

** *Participants who scored the two most positive answering categories (good and excellent) were considered as satisfied patients.*

By using the EUROPEP instrument, Petek et al. conducted a study in eight European countries in 2009. The study aimed to describe evaluations of general practice care by patients with a chronic illness. The MSRs ranged from 82.1% to 93.0% in the European countries [15]. It may be questionable that the study was conducted with a single group of chronic care patients. While a study reported that better health status was associated with a more positive evaluation of care, another study showed that patients reporting a chronic condition were more positive in their assessment of the general practice than patients without a chronic condition [16,17]. However, conducted by Rosemann et al., a previous study utilizing the EUROPEP instrument revealed that patient satisfaction was not determined by the disease-specific quality of life, at least not in osteoarthritis patients [18]. The Turkish Ministry of Health conducted a study in 2010 that surveyed 34472 patients across Turkey. The study aimed to measure patient satisfaction with PHCCs. The MSR was found to be 77.8% with the EUROPEP instrument [19]. The MSR of the current study (67.1%) is lower than that of the previous studies conducted in European countries and Turkey with similar methodology.

In contrast to some other studies, this study found that female patients' satisfaction levels were lower than those of the males [12, 16, 20]. On the other hand, the gender results of this study were consistent with the previous studies conducted in the military settings that found male patients to be more satisfied than female patients [21, 22].

Similar to the study conducted by Petek et al., no difference was found according to marital status in this study [15]. On the other hand, Baltaci et al. observed that the patient satisfaction level was higher for married patients than it was for the unmarried [20].

****Mann-Whitney U test and Kruskal-Wallis test were performed ([a] p<0.05).*

In contrast to other studies, this study found that younger age was associated with higher levels of patient satisfaction. [15, 16]. However, it is worth bearing in mind that the participants in this study were aged 40 or under.

A previous study conducted in a military setting revealed that waiting times were significantly correlated to overall patient satisfaction [23]. The current study found a difference in the satisfaction levels according to the troops the patients belonged to. In the military setting where the current study was conducted, according to the rules, the patient should visit PHCC with the other patients of his/her troop at the same time in the morning, except for emergencies. As the number of patients in the troop increases, the waiting time in the PHCC extends, which may be the underlying reason for the low patient satisfaction level in crowded troops like troop-A.

The current study couldn't confirm the results of previous studies that there is a positive association between the number of visits and the level of patient satisfaction [15, 16]. A majority of the participants of this study (85.9%) had a low number of visits (≤4), and the mean number of visits was 2.6. In Turkey, the total number of visits per person to a general practitioner in 2017 was 2.9 [24].

In this study, it was observed that there was a difference in the satisfaction levels depending on the doctor providing the care. While Dr-A is a military general practitioner, Dr-B is a civilian general practitioner, which may be one of the reasons for the low satisfaction levels of patients evaluating Dr-B.

A strength of this study is that it was conducted with a large population sample. On the other hand, there are relatively several limitations to the study. Because the study was conducted in a military setting, participants were younger than 40 and most of the visits to PHCC were due to acute health disorders. Due to the limited number of general practitioners working in PHCC where the study was conducted, the participants were able to evaluate two doctors in terms of general practice care.

This study highlights the low patient satisfaction levels, which may have resulted from the fact that the study population was young and relatively healthy, and that there was no possibility of choosing the general practitioner and PHCC. However, according to the results obtained through the questionnaire, taking necessary actions to promote patient satisfaction will improve the quality of primary health care in this military setting.

The EUROPEP questionnaire, which is an internationally validated and standardized instrument for patients' evaluations on general practice care, provides feedback to general practitioners and policymakers. The results of a study conducted with this instrument can be directly compared with other studies conducted with the same instrument. These comparisons can shed light on the similarities and differences between various PHCCs. This instrument can also be used to improve primary health care in military settings.

Assessment of traumatic injuries in 1028 patients referred to the Ayatollah Taleghani Hospital from the Sarpul-Zahab earthquake

Fathollah Ahmadpour[1], Shahriar Fazelinezhad[1], Hooman R. Saravi[2], Hadi Khoshmohabbat[1], Sadrollah Mahmoodi[1], Shahram Manoochehry[1], Hamid Reza Rasouli[1]

Abstract: *Introduction: Investigating and recognizing the epidemiological structure of earthquake damages in earthquake-prone countries is of great importance. The aim of this study was to evaluation of traumatic injuries in1028 patients referred to the Ayatollah Taleghani Hospital from the Sarpul-Zahab earthquake (November 12, 2017).*

Method: This study is a cross-sectional study that includes 1028 traumatic patients from the Kermanshah earthquake. The patients, including outpatients in the emergency department, admitted in orthopedic, general surgery and neurosurgery, or even patients who needed to be transferred to other treatment centers.

Result: Of the 1,028 patients, 488 were men (47.5%). The number of men with high injury severity was 51 (10.4%) and the number of women with high severity of the injury was 58 (10.7%). The average age of the injured was 33.04±15.01 years. The mean ISS measure in this study was 8.9±1.6. A total of 109 (10.6%) had scores above 17. The number of cases with head and neck injury was 328 (24%), 233 cases (17%), chest 114 (8.3%), The abdomen or pelvis is 190 (13.9%), the spine is 200 patients (14.6%). After examining the type of trauma in 1791 injuries, 1074 injuries (59.9%) had penetrating trauma and 717 injuries (40.1%) of blunt trauma were calculated. Of patients with severe trauma, 83 patients suffered severe injuries (7.7%) and in patients with blunt trauma, 68 patients suffered severe injuries (9.4%). The mortality rate was 5 (0.5%).

Conclusion: This study established a fracture pattern in the referred patient of the Sarpul-Zahab earthquake to the Ayatollah Taleghani Hospital and is practical for clinicians to increase understanding of this natural disaster and permits superior selection of the triage management and therapeutic process.

Keywords: *earthquake, disaster, trauma, Kermanshah*

INTRODUCTION

Trauma is the most common cause of morbidity and mortality in the first third of life in human societies [1-3]. In recent years, trauma has always been one of the three main causes of injury and general mortality [4]. The distribution of incidence of natural disasters is different in the various regions of the world. There are more than a few potent geographical regions for trauma experiences, such as earthquakes, organized violence, terrorism, combats, and other natural disasters [5-6]. In the past few decades, Iran has experienced more than a few earthquakes, which caused severe and massive damages. Therefore, investigating and recognizing the epidemiological structure of earthquake damages in earthquake-prone countries such as Iran is of great importance. On November 12, 2017, an earthquake

take place in Sarpul-Zahab and Sallatha Babajani cities, Kermanshah Province, Iran, with a 6.9-magnitude on the Richter scale. The urban and population density areas were exposed due to this earthquake for significant severe and massive damages. The fracture pattern in injured patients due to earthquakes is different in the various regions of the world, for example, in the earthquake of Armenia, the head and neck injury rate was 22% [7]. In the Wenchuan earthquake, the highest number of injuries has been seen in those who suffered damage to the external surface of the body [8-9]. Generally, the fracture pattern of an earthquake can be including simple morbidity, to even mortality. Therefore, characterization of the mechanism and epidemiologic variables of these traumatic events is necessary for the management of proper initial triage [10].

The aim of this study was to evaluation of traumatic injuries in1028 patients referred to the Ayatollah Taleghani Hospital from the Sarpul-Zahab earthquake (November 12, 2017) regarding different levels of demographic variables (age and gender), pathology of the disease (anatomical location of the injury, type of trauma, triage level, etc.) and the stages of treatment (how the patient transmits, operating care, etc).

METHODS

This study is a cross-sectional study that includes traumatic patients from the earthquake in Kermanshah province on November 12, 2017, referred to the Ayatollah Taleghani Hospital of Kermanshah as the largest treatment center in the west of Iran. The study population included 1028 patients, including outpatients in the emergency department, admitted in orthopedic, general surgery, and neurosurgery, or even patients who needed to be transferred to other treatment centers.

Data analysis including frequency varying levels, the percentage of damage to the severity of the trauma for variables such as age, sex, type of trauma, and injury as well as the correlation between trauma severity and anatomical location of some of the variables. After the initial studies, the patients' medical records were filled in for two months.

The severity of trauma by ISS method according to the AIS criteria for traumatic patients with a proper pre-study was carried out. To calculate the patient ISS, the body is divided into six parts as follows:

Head and neck
Face
Chest
Abdomen or pelvis
Spinal cord
Limbs

To calculate the ISS, the highest severity of AIS is considered in the three areas of the body that have seen the most damage, then we squeeze three AIS scores together to calculate the severity of the ISS damage. AIS scoring is based on the amount of injury and the anatomical location of the damage between 1 and 6, which is 1 indicates minor damage and 6 is the number of fatal injuries. Hence, the severity of the ISS damage is between 1 and 75, since by eliminating deadly injuries with a score of 6, the sum of the squares of other AIS levels is 75 (25 + 25 + 25 = 75), 75 (25 + 25 + 25), the injuries that the IIS is 6, 75 are considered [6, 13, 14]. Registered demographic data allow the proportion of male and female patients or the age range of patients to be identified in terms of the severity of the injury. The structure of the damage is also known by its characteristics, such as trauma, triage, and anatomical location. The protocol of the study was approved by the ethical committee of Baqiyatallah University of medical sciences.

Data analysis was performed using SPSS-20 software. Descriptive statistics such as frequency, percent, mean and standard deviation were presented.

RESULTS

1028 patients transferred to Ayatollah Taleghani hospital were included in the study. Table 1 depicts patients' characteristics regarding transition status, sex, age levels, Anatomic location of the injury, Triage level, Type of trauma, Duration of admission, ISS, and outcomes (Table 1). Of the 1,028 patients, 488 were men (47.5%). The number of men with high injury severity was 51 (10.4%) and the number of women with high severity of the injury was 58 (10.7%). The ratio of women with high severity of the injury was 5.6% for all patients and 4.9% for men. The average age of the injured was 33.04±15.01, range from 1 to 95 years.

Table 1: Patients' characteristics regarding transition status, sex, age levels, Anatomic location of the injury, Triage level, Type of trauma, Duration of admission, ISS, and outcomes

Variable	N	%
Transition status		
Emergency	354	34.4
Personal car	420	40.9
Other ways	254	24.7
Sex		
Male	488	47.5
female	540	52.5
Age		
0-4	56	5.4
5-14	59	5.7
15-24	136	13.2
25-44	410	39.9
45-64	242	23.5
>65	125	12.3

Variable	N	%
Anatomic location of the injury		
Head and neck	328	18.3
Face	233	13
Chest	114	6.3
Abdomen and pelvis	190	10.7
Spine and Spinal cord	200	11.2
Limb	726	40.5
Triage level		
1	2	0.2
2	470	45.7
3	534	52.0
4	22	2.1
5	0	0.0
Type of trauma		
Penetrating	1074	59.9
Blunt	717	40.1
Duration of admission		
1 day	676	65.8
1-7 day	328	31.9
7-30 day	22	2.1
>30 day	2	0.2
Operational care		
Emergency clearance	527	51.3
Orthopedic surgery	349	33.9
General surgery	109	10.6
Neurological surgery	43	4.2
The outcomes		
Partial recovery	733	71.3
Die	5	0.5
Transfer to another hospital	189	18.4
Other	101	9.8
ISS		
1-7	578	56.2
8-16	341	33.2
17-25	71	6.9
>25	38	3.7

The mean ISS measure in this study was 8.9±1.6, ranging from 1 to 75. A total of 109 (10.6%) had scores above 17.

The total of injuries for 1028 patients was 1,791 injuries, according to the anatomical status of injury, the number of cases with head and neck injury was 328 (24%), 233 cases (17%), chest 114 (8.3%), The abdomen or pelvis is 190 (13.9%), the spine is 200 patients (14.6%). The organs are 726 cases (53.3%) (Table 2).

Table 2: Frequency of different anatomic location groups of damage in the ISS levels

		ISS				
		1-7	8-16	17-25	>25	Total
Anato	Head and neck	136	99	54	39	328
	Face	104	98	21	10	233
	Chest	43	50	14	7	114
	Abdomen or pelvis	66	62	30	32	190
	Spinal cord	83	62	25	30	200
	Limbs	489	161	51	25	726
	Total	921	532	195	143	1791

The division of patients in terms of the age group showed that the highest number of patients was in the age group of 25-44 years, and the lowest number of patients was in the age group of 0-4 years. This severity of injury shows that the severity of injury in the age group of 15 to 24 years has the highest proportion compared to other groups (Table 3).

Table 3. Frequency of different age groups and frequency of severe injuries in groups

		Frequency	Frequency percent	Percentage of damage
Age	0-4	56	5.4	3.5
	5-14	59	5.7	6.7
	15-24	136	13.2	12.5
	25-44	410	39.9	11.4
	45-64	242	23.5	8.6
	>65	125	12.3	14.4

After examining the type of trauma in 1791 injuries, 1074 injuries (59.9%) had penetrating trauma and 717 injuries (40.1%) of blunt trauma were calculated. Of patients with severe trauma, 83 patients suffered severe injuries (7.7%) and in patients with blunt trauma, 68 patients suffered severe injuries (9.4%). The mortality rate was 5 (0.5%).

DISCUSSION

Earthquakes are administered in different methods, according to particular regions and countries [11]. In the past few decades, Natural disasters have affected 800 million people, and have caused over $500 billion of economic costs [12-14].

In recent decades, various methods have been used to evaluate the severity of the trauma, including ISS, TRISS, etc. In this study, the ISS method was used and we examined the severity of trauma with other variables. Being the benchmark used in this article, ISS is a global traumatic survey criterion defined based on the sum of the three injuries with the highest AIS score. ISS is usually divided into 6 areas per person and is also used for patients with more than one injury. The numerical value of this numerical criterion is between 1 and 75, with scores less than 7.5 categorized in the group of weak injuries, scores between 7.5 to 17 categorized in the group of moderate injuries, and scores more than 17 categorized in the group of severe injuries. Traumatic studies and epidemiological structure of the trauma caused by the earthquake led to the classification of vulnerable groups and the identification of vulnerable anatomical parts of the body in injured people. This knowledge informs us about the necessary steps to prevent further problems and to deal with the damage that has been caused.

In this study, five mortality (2 female and 3 male patients) were seen that have multiple trauma and blunt abdominal trauma. 60 % of the dead were between the ages of 25-45. The severity of injury for all of them was higher than 25, with an average injury severity of 38.4. this mortality can reduce if the management of triage was done with the standard method, for example, Sonography in Trauma (FAST) can be regarded in the administration of disaster management, that it can reduce mortalities due to blunt abdominal and multiple traumas, as Kakaei et al. [15] reported on the value of FAST as a primary diagnostic method for revealing of blunt abdominal and multiple trauma. Therefore, conducting FAST is a primary screening with high speed that can use in situations of disaster. The impotence of the FAST as a primary diagnostic method has been confirmed in the previous studies for primary screening [16].

The administration of triage of patients is one of the most important episodes of disaster management, hence, it has been indicated that triage of injured patients in disastrous events, particularly earthquakes, can decrease considerably mortality and morbidity. The accessibility of hospitals is very significant in disaster administration after earthquakes, and this subject is related to the structure of the hospital and building standards [17]. In this study, we have few mortality (5 cases), because the administration of triage of patients was done correctly, and the hospital was accessible and all the patients were established on the same crisis day. Although, in the Bam earthquake, the patients were triaged during the night following the disaster, since the two main hospitals of Bam were destroyed [18].

In this study, the demographic results established that trauma was more common in females (52.5% for females and 47.5% for males), and 39.3% of the patients have 25-44 years. The several studies indicated comparable outcome with these in the different regions of the world however In the Pakistan earthquake, 60.7% of the patient was male and 39.3% were female and 49% of patients have 25-44 years [19] because the most population of this region are in the third decade of life.

In this study, the age range of the patients was 1-95 years with a mean of 33.4 years. In the Marmara earthquake, Turkey, the age range of the patients was 11-74 years with an average of 34 years.

Limb injuries are the most common trauma in earthquake injuries, in this study, 42% of patients have presented limb injuries that the previous studies indicated similar outcomes, as 39% of the patients suffered head and neck injuries in the Armenia earthquake [8-11]. In our study, the most frequent area exposed for injury was limbs (42%) and followed by head and neck (18%), face (12.7%), abdomen and pelvis (10.5%), chest (5.9%). Also, the most common area exposed for injury was limbs (38.5 %) and followed by chest (21.4%), abdomen and pelvis (15.2%), spine (9.5%), head and neck (7.9%), face (1.3%) in the Wenchuan earthquake. In the Bam earthquake, 68% of the organs were damaged, compared to 42% in our study. Because the Bam earthquake occurred more time than this earthquake, also the strength of the Bam earthquake was higher due to the surface of the earthquake center [12, 20-24].

CONCLUSION

This study allows us to assess and manage the crisis, trauma due to earthquake, epidemiology of earthquake trauma. The results of this study confirmed with studies of other earthquakes in the world, however, some results different since this study was conducted to determine the epidemiological structure of the trauma, the issues which haven't been discussed in the literature. Consequently, this study established a fracture pattern in the referred patient of the Sarpul-Zahab earthquake to the Ayatollah Taleghani Hospital and is practical for clinicians to increase understanding of this natural disaster and permits superior selection of the triage management and therapeutic process.

Association of rare disease and acute intoxication – case report

Radu A. Macovei[1,2], Radu C. Ţincu[1], Mihail S. Tudosie[2]

Abstract*: Benzodiazepine overdose has various clinical manifestation, mainly regarding the central nervous system (CNS), cardiac and respiratory side effects, but rarely results in significant morbidity and mortality. Acute benzodiazepine poisoning results in dizziness, ataxia, nystagmus, dysarthria, hypoxia, hypothermia, bradycardia, hypotension, apnea, pulmonary aspiration, respiratory depression, coma, cardiopulmonary arrest and death. Anyway, deep nonresponsive coma should be investigated for additional etiologies. On the other hand, human transmissible prion disease has a fatal outcome with no specific treatment.*

Keywords: *prion disease, benzodiazepine intoxication, opisthotonus*

Human transmissible prion diseases are neurodegenerative disorders characterized by infectious pathogens accumulation with a long incubation period and devastating outcomes. A prion is defined as a small infectious agent lacking of nucleic acid, but containing protein [1]. It has an important feature regarding resistance to a number of decontamination procedures including processes affecting nucleic acids such as hydrolysis [2]. Up to present, human pathology recognize five related entities: Creutzfeldt-Jakob disease (CJD), Kuru, variant Creutzfeldt-Jakob disease (vCJD also known as new variant CJD), Gerstmann-Sträussler-Scheinker syndrome (GSS), and fatal familial insomnia (FFI) [3].

Prionopathies result from abnormal isoforms accumulation in the brain that leads to neuron apoptosis and important brain damage. Infective prion is a product resulting from defective folding of the normal prion, having the gene located on the short arm of the chromosome 20 [4]. Unfortunately, the prognosis is very poor in these patients, despite all efforts and sustained interventions.

Benzodiazepines are commonly used against various disorders such as insomnia and anxiety. They also are preferred agents for drug overdose, although their acute toxicity is low. Oral benzodiazepine intoxication rarely results in

[1] Intensive Care Unit, Clinical Emergency Hospital Bucharest, Bucharest, Romania

[2] Carol Davila University of Medicine and Pharmacy, Bucharest

significant morbidity and mortality. The body develops tolerance against such effects in the course of time and most common side effects are sedation and ataxia. Anxiolytic effects is rarely implicated in tolerance development. Acute benzodiazepine poisoning may result in dizziness, ataxia, nystagmus, dysarthria, hypoxia, hypothermia, hypotension, bradycardia, apnea, pulmonary aspiration, respiratory depression, coma, cardiopulmonary arrest and death.

CASE PRESENTATION

We present the case of a young white female, aged 26, admitted in our Toxicology – Intensive Care Unit of Clinical Emergency Hospital Bucharest from Bucharest, the capital of Romania. She was referred to us after deliberate ingestion of 200 mg benzodiazepine associated with 500 mg metoprolol. Ten months before this event the patient experienced complaints such as mood disorders, memory loss, irritability, inability every day social behavior and insomnia; initially, the condition was assessed as depression but no certain treatment was recommended. We couldn’t find any history of visual hallucinations or tremor. Interview emphasized multiple study visits in the United Kingdom and occasionally intravenous abuse substances dependence. Any other past medical data were unremarkable. The first medical examination revealed a conscious patient, mild agitated, stable vital signs, with unusual hyperosmia and visual impairment. Toxicology assessment was positive for benzodiazepine in the urine, detected with fluorescence polarization immunoassay method; toxicological screening was negative for other drugs. She had a rapid unfavorable evolution the following hours after admission experiencing degenerative progression of psychomotor and cognitive functions, lack of hand-eye and alternating hand coordination, left hand tremor and left lower extremity weakness and in the end, ten hours after ingestion, she developed impressive opisthotonus and deep coma that required mechanical ventilation. The evolution was unexplained by her toxicological status and occurred unexpectedly. Brain tomography was in normal ranges (Figure 1). She was performed lumbar puncture and the cerebral fluid features included clear aspect, normotensive, with glucose and electrolyte levels within normal limits and no type of cell detection. Regarding highly suspicion of tetanus, due to her occasionally intravenous drug administration, the infectious disease evaluation indicated anti-tetanus serum therapy, but clinical evolution wasn’t improving. After 48 hours of nonresponsive evolution a new brain CT scan identified massive cerebral edema. Cranial MRI showed marked cerebral atrophy in frontoparietal areas, DWI hyperintensities (cortical ribboning) in basal ganglia bilaterally and diffusion restriction in these areas suggesting progressive multifocal leukoencephalopathy, whereas putamen and caudate nucleus were free of signal intensity (Figure 3). Considering these aspect, we performed PCR for the detection of JC virus which was negative. A prionic disease was highly suspected and 14-3-3 protein immunoassay on CSF was positive. The patient died after 2 months in Critical Care Unit due to multiple dysfunctions, with the diagnostic of Creutzfeldt-Jakob disease.

DISCUSSION

As a part of the prionic disease family, CJD evolution is characterized by rapid evolution and neurological deterioration. The majority of cases are represented by sporadic human prion diseases, while 1-2% of the remaining are infectious forms acquired from an established source with the prion disease and 5-15% is represented by the autosomal dominant type [1]. The presented case exhibits most of the sporadic CJD clinical features with rapid cognitive decline and mioclonus; MRI was an indispensable tool for differential diagnosis considering that DWI hyperintensities in the putamen, caudate and cortex have a high specificity for sporadic prion disease [6]. However, the short dramatic course of the disease and detection of protein 14-3-3 in CSF adds value to diagnostic criteria. The literature shows that the mean age of onset is around 65 years of age with a very short median survival time around four months [7], but we report an extreme age (eg. 26 years old).

CONCLUSIONS

The case presented in this paper was meant to describe the clinical progression of a rapid evolving encephalopathy in a patient admitted for benzodiazepine ingestion. It also underlines the importance of keeping an open mind when dealing with unexpected and unusual evolution of acute intoxication.

REVIEW

A systematic review on a comparison between intravenous paracetamol and intravenous morphine sulfate for management of patients with trauma injuries

Ali Ebrahimi[1], Mohammad R. Ghane[1], Seyed N. Naghibi[1]

Abstract: *Introduction – Pain is known the most common complaint in emergency departments. Several studies are administered many different protocols to control pain in trauma patients. The aim of the study was to review the major relevant articles in case of application of intravenous paracetamol and intravenous morphine sulfate for management of patients with trauma injuries.*

Methods – We searched the online databases such as PubMed, MEDLINE, EMBASE, ISI Web of Knowledge. We applied keywords included pain, acute, chronic, morphine sulfate, paracetamol, trauma, limb, wounds, and injuries, damage and etc.

Results – We included four eligible randomized clinical trials in this study. Three studies reported superior effects in intravenous paracetamol compared to intravenous morphine sulfate in controlling pain in trauma patients (limb trauma and trauma headache). However, a study reported no significant differences between the two groups in knee arthroscopy in trauma patients. All studies used from VAS methods for measurement of pain score.

Conclusion – The results indicated that IV paracetamol presents a superior analgesia than IV morphine sulfate particularly after acute limb trauma and trauma headache. However, further studies should be done that clinician could be have better decision for control pain in trauma patients.

Keywords: *intravenous, paracetamol, morphine sulfate, pain, trauma injuries*

INTRODUCTION

Pain is known the most common complaint in emergency departments [1, 2]. Studies have reported about 70% of all patients attending emergency departments to suffer different levels of pain. Several studies are administered many different protocols to control pain in trauma patients [3-7]. However, stand for an ideal suggestion for an analgesic to be administered as the main part of the treatment is a debatable issue yet [4, 7, 8].

Regarding control different levels of in both acute and chronic pain, opioids have many beneficial [9, 10]. Morphine sulfate has known the prototype utilized in patients suffering from different levels of pain because of trauma injuries [8, 11, and 12].

Morphine sulfate has an acceptable analgesia by several controlling modalities in the trauma patient for controlling acute pain [11]. However, several complications such as constipation sedation, confusion, miscellaneous neuro-psychological symptoms, nausea/vomiting and respiratory depression & hallucinations have been reported in patients taking morphine sulfate intravenously [13]. Considering some limits and side effects may result in applications in order to quest for more efficient and less disadvantageous alternative analgesics [4, 8, 14].

N-Acetyl-p-Aminophenol which is acknowledged as paracetamol is an inhibitor of cyclooxygenases which has been recognized globally as a safe and effective substance for pain drug and decreasing fever [12-16]. Paracetamol is one of the leading generally used analgesic and antipyretic factors. Since 2001, intravenous paracetamol has been available in Europe under the trade name Perfalgan and is accessible in many countries [15]. It is generally applied for reducing different rates of the pain of trauma patients from

mild to moderate [15]. Also, it is used to control fever in neonates, children, and adults [8, 15, 17].

Studies reported paracetamol has fewer complications than opioids or nonsteroidal anti-inflammatory drugs (NSAIDs) [8, 12]. Studies have reported several complications such as opioid administration such as nausea, emesis, histamine release/pruritus, hypotension, sedation, respiratory depression, and constipation following administering this analgesic [16]. Also, hepatotoxicity may happen as a consequence of overdose or exceed therapeutic dosage medicine [15, 16].

Several investigations were carried to analyze the effectiveness of applying paracetamol and morphine either in separated groups or in combination with each other or alternative adjuvant therapy, including postoperative pain relief, cancer pain control or intravenous regional anesthesia [14-17]. A few studies are carried to study the comparative efficacy of prescription of morphine sulfate versus paracetamol in trauma injuries [8, 12]. So it should be realized that further studies may be required to confirm the findings. In this study, we aimed to review the major relevant articles in case of application of intravenous paracetamol and intravenous morphine sulfate for management of patients with trauma injuries to support clinicians to have a better understanding of these technologies and choosing the better healing choice.

METHODS

We searched the online databases such as PubMed, MEDLINE, Wiley, EMBASE, ISI Web of Knowledge and Scopus. We applied keywords included pain, acute, chronic, morphine sulfate, paracetamol, trauma, limb, wounds, and injuries, damage and etc. All relevant randomized clinical trial studies were included in this study. Two reviewers independently searched and evaluated the titles and abstracts of all articles.

RESULTS

In a randomized, clinical trial by Vahdati et al. (2014) evaluated the analgesic and safety of paracetamol compared to morphine in the management of a headache in patients with a trauma headache. Patients were randomly classified into two groups to get either intravenous paracetamol [Apotel 1 g (paracetamol 1 g made by Unipharm factory, Greece) normal saline (1 g/100 mL/10 minutes)] or morphine (0.1 mg/kg/100 mL/10 minutes NaCl). They concluded intravenous paracetamol is an effective and safe treatment than morphine [16].

Craig et al. (2012) compared the effect of intravenous paracetamol versus morphine in patients with moderate to severe traumatic limb pain. They included patients (16 to 65 years) with isolated limb trauma and in moderate to severe pain (pain score of 7 or more) received either 1 g intravenous paracetamol or 10 mg intravenous morphine sulfate over 15 min. They measured pain score via visual analog scale at 0, 5, 15, 30 and 60 min following beginning drug treatment. They reported there was no difference in analgesic effect and rescue analgesia between the two groups at any time interval. But there were significantly more adverse reactions in the morphine group than the paracetamol group. They concluded intravenous paracetamol seems to give a level of analgesia comparable to intravenous morphine in isolated limb trauma patients [17].

Jalili et al (2016) did a randomized double-blinded clinical trial for comparison of intravenous 0.1 mg/kg morphine sulfate with 1 g intravenous paracetamol in order to pain reduction in sixty patients with pain score of greater than 3/10 in the limb trauma. They reported the mean pain intensity scores for paracetamol (3.86) and for morphine (2.16) ($P < 0.001$). 15 patients (morphine group) plus four patients (paracetamol group) required rescue analgesia ($P = 0.05$). They concluded that IV paracetamol present superior analgesia than IV morphine in these traumatic patients. However, further studies should be done that confirms this issue [18].

Hashemi et al (2015) evaluated comparison of IV paracetamol with morphine for the pain administration after diagnostic knee arthroscopy in sixty traumatic patients in a randomized double-blinded clinical trial. They measured the nausea and vomiting, pain level, and sedation. They reported no considerable difference between the two groups regarding to the pain level. The complications were not seen in the paracetamol group; although, the postoperative nausea was seen in 22.3% of PCA morphine group. Hashemi et al presented clinical advantages for IV paracetamol including stable hemodynamic parameters, reduction of analgesics management, improved postoperative pain, no nausea and vomiting, lower complications, reduction length of hospitalization, and increased patient comfort and satisfaction [19].

Dijkstra et al (2013) did a systematic review in order to recognize efficient and safe primary pain interventions for traumatic patients with acute pain in the chain of emergency care, accessible in the Netherlands. They reported that Paracetamol (both IV and orally) and IV opioids (fentanyl and morphine) comfirmed to be efficient. They not recommended non-steroidal anti-inflammatory drugs (NSAIDs) for use in pre-hospital ambulance or emergency medical services because NSAIDs showed mixed results [20].

Table 1: Characteristics of the reviewed studies

Author(s) (year)	Medication	Design	Trauma	N	Setting	Pain score outcome measure	Pain relief results	Conclusion
Jalili et al (2016) [18]	intravenous 0.1 mg/ kg morphine sulfate with 1 g intravenous paracetamol.	randomized double-blinded clinical trial	Limb Trauma	60	trauma center of a university hospital (emergency department)	VAS	The mean reduction in numerical rating scale pain intensity scores at 30 minutes was 3.86 (± 1.61) for paracetamol, and 2.16 (± 1.39) for morphine	They concluded that IV paracetamol present superior analgesia than IV morphine in these traumatic patients. However, further studies should be done that confirms this issue
Hashemi et al (2015) [19]	intravenous infusion of 1 g paracetamol within 15 minutes after surgery and every 6 hours to 24 hours in the paracetamol group. The patient-controlled analgesia group received morphine through PCA infusion pump at 2 mL/h base rate and 1mL bolus every 15 minutes. Pain level, nausea and vomiting, and sedation were measured and recorded during entering the recovery, 15 and 30 minutes after entering the recovery, 2, 6, and 24 hours after starting morphine pump infusion in the morphine and paracetamol in the paracetamol groups.	randomized double-blinded clinical trial	knee arthroscopy in trauma patients	60	trauma center of a university hospital (tertiary hospital)	VAS	They reported no considerable difference between the two groups regarding to the pain level. The complications were not seen in the paracetamol group; although, the postoperative nausea was seen in 22.3% of PCA morphine group	Hashemi et al presented clinical advantages for IV paracetamol including stable hemodynamic parameters, reduction of analgesics management, improved postoperative pain, no nausea and vomiting, lower complications, reduction length of hospitalization, and increased patient comfort and satisfaction
Vahdati et al. (2014) [16]	intravenous paracetamol [Apotel 1 gr. (paracetamol 1 gr. made by Unipharm factory, Greece) normal saline (1 g/100 mL/10 minutes)] or morphine (0.1 mg/kg/100 mL/10 minutes NaCl).	randomized, clinical trial	Trauma Headache	60	trauma center of a university hospital (tertiary hospital)	VAS	After 15 minutes, pain was 31.7 ± 18.0 and 48.3 ± 14.1 mm in Paracetamol and Morphine Respectively (P<0.005).	They concluded intravenous paracetamol is an effective and safe treatment than Morphine
Craig et al. (2012) [17]	1 g intravenous paracetamol or 10 mg intravenous morphine sulfate over 15 min.	randomised, double-blind pilot study	traumatic limb	55	Emergency department	VAS	After 60 minutes, pain was 52.9± 27.4 and 44.0± 22.6 in Paracetamol (and Morphine Respectively (P=0.28).	They concluded intravenous paracetamol seems to give a level of analgesia comparable to intravenous morphine in isolated limb trauma patients

DISCUSSION

Efficient management of pain is an important concern for anesthesiologists. The patients still endure insufficient postoperative pain administration in spite of the progression of pain control methods. The management of pain by opioids has some complications such as vomiting, nausea, urinary retention, pruritus, and respiratory depression [21]. Consequently, the non-opioids have become more accepted to avoid of these complications [22]. Hashemi et al reported that paracetamol and morphine equally reduced the intensity of postoperative pain. Decreasing of opioids usage is crucial for the reason that it dues to a reduction in complications and side-effects. In addition, any method that reduces admittedly total opioid consumption dose is considered an advantage. It demonstrated that intravenous paracetamol be as successful as ketorolac, diclofenac, and morphine in the some clinical studies. Therefore, it is favorable for the management of moderate to severe pain after surgery [23, 24].

The correct mechanism of function of paracetamol has not been found. The paracetamol might cause activation of serotonin receptor II and subsequently prevention of cyclooxygenase pathway for the production of prostaglandins with double-barreled impacts [25-27]. The paracetamol can be related to bleeding complications through preventing the synthesis of prostaglandins and associated compounds [25]. Paracetamol may possibly reduce peripheral vascular resistance and cardiac output [28]. Hashemi et al presented clinical advantages for IV paracetamol including stable hemodynamic parameters, reduction of analgesics management, improved postoperative pain, no nausea and vomiting, lower complications, reduction length of hospitalization, and increased patient comfort and satisfaction.

Different studies discuss the advantages of IV paracetamol such as; Sinatra et al [29] reported that IV paracetamol is a valuable analgesic, although Haddow et al [30] commented that it is more readily accessible than morphine, which is an effective and restricted drug. Todd et al [31] demonstrated that no difference between IV morphine and IV paracetamol in the analgesic effects on patients. Also, Van Aken et al [32] demonstrated that IV paracetamol is superior tolerated after dental surgery. Craig et al [33] demonstrated that approximately no difference in pain scores for comparison of the effects of 10 mg of IV morphine with 1 g IV paracetamol in the UK ED patients. Paracetamol can reduce opioid supplies by between 20% and 30% because it is an efficient adjunct to opioids [34]. The researches indicated that IV morphine would have intensified the iatrogenic influences of fentanyl, especially its potential to cause respiratory depression and hypotension, while IV paracetamol be able to decrease the amount of fentanyl required [35].

Institute for Clinical Systems Improvement reported that paracetamol is extensively applied in clinical practice and is an effective safe, simple, and analgesic with few side effects. Hoogewijs et al and Viallon et al [36-37] reported that intravenous management of paracetamol in the ED seemed to have a quicker beginning, while paracetamol controlled p.o. does not need an i.v. catheter supplement and is consequently easier and less time-consuming for emergency care professionals. Feldman et al indicated rectal usage of paracetamol has a inconsistent bioavailability, and it cannot be simply appropriate in pre-hospital emergency conditions; consequently, this method of management is not suggested in emergency care. Dijkstra et al reported that Paracetamol and opioids including morphine and fentanyl proved and verified to be effective and safe analgesics for trauma patients [20].

Jalili et al demonstrate and suggested that acetaminophen is a safe and effective nonopioid analgesic for ED patients with acute traumatic limb pain. They showed IV morphine sulfate is efficient for pain administration in these patients, although 1-gram dose of IV paracetamol presented a superior level of analgesia comparison to morphine. In the other hand, the morphine consumption is considerably lower in the paracetamol group [18]. Several studies confirmed prospective efficiency of intravenous paracetamol in acute pain administration. Nevertheless, the majority of them demonstrated that the analgesic outcome of IV paracetamol is analogous to effect of IV morphine sulfate. Craig et al comprised IV paracetamol and IV morphine sulfate for pain administration of acute limb trauma in the ED, they showed no considerable difference in analgesic outcome between the morphine and paracetamol groups at any time point [33]. However, amount of morphine sulfate was greater than the used morphine dose by Jalili et al. Bektas et al. evaluated the analgesic outcome of IV morphine and IV paracetamol for the cure of renal colic, while were observed no considerable reductions in the pain intensity between paracetamol and morphine group [38]. Sinatra et al. assessed the safety and efficacy of paracetamol for pain administration following major orthopedic surgery [38]. They reported the pain intensity scores for consumption of paracetamol and morphine is considerably reduced while no complications were seen during 24 hours after surgery in comparison to the placebo group [38].

CONCLUSIONS

The results indicated that IV paracetamol presents a superior analgesia than IV morphine sulfate particularly after acute limb trauma and trauma headache. However, further studies should be done that clinician could be have better decision for control pain in trauma patients.

REVIEW ARTICLE

Atherosclerosis in rheumatoid arthritis – the importance of imaging tests

Oana P. Ionescu[1], Silviu M. Stanciu[1], Mihai L. Ciobîcă[1]

Abstract: *As reported by literature, rheumatoid arthritis is a rheumatic disease with an increased risk of developing cardiovascular complications. Early detection of atherosclerosis by non-invasive techniques represent a current challenge of patient management. Current EULAR guidelines recommend careful monitoring of cardiovascular risk factors by stratification of patients and strict control of rheumatic disease activity to reduce it. The classic evaluation of intima-medium thickness (IMT) was completed by quantifying the degree of inflammation of the carotid plate using positron emission tomography or the degree of coronary calcifications by calculating Agatston score using Coronary Computer Tomography. These modern investigation techniques allow identification of several subclinical stages of atherosclerosis, the interest in their early detection resulting from the fact that, in this stage, through specific measures, the cardiovascular complications can be prevented.*

Keywords: *rheumatoid arthritis, atherosclerosis, cardiovascular risk, imaging tests*

INTRODUCTION

Rheumatoid arthritis is a rheumatic disease with an increased risk of cardiovascular events due to advanced atherosclerosis [1]. The development of atheromatous plaque is based on chronic inflammation found in both rheumatoid arthritis and atherosclerosis[2]. Recent studies have shown a higher prevalence of plaque in patients with rheumatoid arthritis, which explains their negative predictive role[3,4]. The higher frequency of traditional risk factors in patients with rheumatoid arthritis (hypertension, type II diabetes, smoking, high cholesterol and obesity) is another factor contributing to the development of cardiovascular complications. Its impact is different from that of the population not suffering of this pathology [5,6]. Current EULAR guidelines recommend careful monitoring of cardiovascular risk factors by stratification of patients and strict control of rheumatic disease activity to reduce it [6]. The early detection of atherosclerotic changes by non-invasive techniques is a current concern of patient management. Collaboration between rheumatologist and cardiologist and prospects of a new specialty - cardio-oncology will be encouraged in future in order to improve the prognosis of patients affected by rheumatoid arthritis and atherosclerosis.

NONINVASIVE IMAGING OF INTRACRANIAL VESSELS

Atherosclerotic plaque is the trigger for cardiovascular events, its vulnerability being due to plaque composition, inflammatory cell content, age, and not necessarily plaque size [7, 8]. In rheumatoid arthritis, advanced inflammation causes a particular phenotype of the plaque, thus presenting an increased risk of myocardial infarction or stroke [9, 10]. Transcranial Doppler examination is a method of measuring cerebral blood flow in the main intracranial arteries. This method uses 2 MHz ultrasound probes to dynamically detect intracranial arteries through thinner areas of the skull called

acoustic windows [11, 12]. This study has proven inexpensive, reproducible and provides information on the prognosis of cardiovascular events [13, 14, 15, 16]. Measurement of average mean cerebral arterial flow rate, pulsatility index, and calculation of the relationship between these two indices revealed prognostic factors of recurrent cardiovascular events [17, 18] In patients with rheumatoid arthritis, there was an increase in the prevalence of distal occlusions of the middle cerebral artery and basilar artery detected by transcranial Doppler [11].

Another investigation commonly used in the clinic is the Doppler ultrasound of the carotid arteries. This is a good way to identify patients with rheumatoid arthritis at high cardiovascular risk who can benefit from active treatment.

Proper stratification of cardiovascular risk is a key element in the management of patients with rheumatoid arthritis. It is well known the EULAR's adaptation of cardiovascular risk assessment based on coronary risk assessment (SCORE) multiplied by 1.5 in patients with rheumatoid arthritis that meet two of the following three criteria: disease> 10 years, rheumatoid risk factor (RF) or anti-cyclic cytoplankin peptide (anti-CCP) antibody and presence of serious extra-articular manifestations [19]. However, the authors recommend performing a carotid ultrasound scan when SCORE (Figure 1)[20] does not report high cardiovascular risk, considering studies in which patients with rheumatoid arthritis were not considered at high risk for cardiovascular events by calculating SCORE risk, but who had significant cardiovascular events: myocardial infarction and stroke [21].

Carotid Doppler ultrasound evaluates intima-medium thickness (IMT) and highlights atherosclerotic plaques, making it an affordable, easy-to-use, reproducible, low cost study. A meta-analysis of 1384 patients with rheumatoid arthritis concluded that a carotid IMT increased from the control group population – 1147 patients (normal IMT <0.9 mm) [22]. Olah C. et al [11] also published in 2017 a study on the assessment of intracranial vessels in combination with carotid atherosclerosis and stroke in patients with rheumatoid arthritis in which more patients with rheumatic disease had at least a plaque in the right carotid artery, and its score was higher than that of the control group patients. Thus, we can say that carotid ultrasound remains an easy-to-use tool in practice, but different protocols for measuring the carotid plaque and operator-dependent, makes this investigation more and more replaced by carotid magnetic resonance.

Carotid magnetic resonance has the advantage of capturing the entire circumference of the carotid wall, including the adventitia and the outer layer, as opposed to carotid ultrasound, which only visualizes the intima of the carotid artery. In the multiethnic study of atherosclerosis, conducted in six US research centers, 698 patients were included and examined by carotid ultrasound and MRI. The results of the study showed that MRI could be a better predictor of cardiovascular events than carotid ultrasound, as the combination of wall thickness measured by magnetic resonance was stronger than that of ultrasound-measured IMT [23]. In addition, the arterial history revealed by MRI seems to be a better predictor of cardiovascular complications in a study that showed an increase in inflammatory cytokine expression in aortic adventitia in patients with rheumatoid arthritis who suffered from coronary artery bypasses compared to control patients [24, 25]. Another advantage of this method of non-invasive diagnosis is the strong correlation with the histological phenotype of atherosclerotic plaque, the dynamic contrast-enhanced MRI (DCE-MRI) allowing to evaluate the neovascularization of the atherosclerotic plaque, its vulnerability by the degree of inflammation and the degree of hemorrhage in plaque, and the effectiveness of therapeutic interventions [26, 27].

Another more modern technique capable of quantifying the degree of inflammation of the carotid plate is positron emission tomography. This exploration uses 18-F-fludeoxy-glucose, a glucose analogue, which has the ability to accumulate in inflamed atherosclerotic plaque, where exists a greater amount of marked pozitrons [28]. Thus, CT or magnetic resonance imaging is possible to map the affected area, the absorption of fludeoxoxiglucose being associated with the identification of lesions at high risk of embolization [29]. Another radioactive agent used in the detection of atherosclerosis is sodium fluoride (18-F-NaF), which is capable of binding to calcified unstable arterial zones. During the course of atherosclerotic disease, two types of vascular damage can occur: macrocalcification – conferring stability to plaque atheroma and microcalcification – associated with an increased risk of plaque vulnerability. Sodium fluoride PET-CT differentiates the two types of lesions presented above, the new technique being able to revolutionize the treatment of atherosclerosis, increasing the chances of preventing cardiovascular complications [30].

NONINVASIVE CARDIAC IMAGING

Advanced atherosclerosis in rheumatoid arthritis is also evident in the heart, manifesting itself in various forms: coronary ischemia - micro and macrovascular, inflammation or myocardial fibrosis (myocarditis) [31]. Rheumatoid arthritis should therefore be closely monitored using non-invasive techniques to identify patients at high risk of developing cardiovascular complications. A recent study performed by a Danish team, which included the entire population over 18 years old diagnosed with rheumatoid arthritis between 1978 and 2008, found an increased risk of heart failure in patients with rheumatoid arthritis, justifying the need for cardiovascular screening [32].

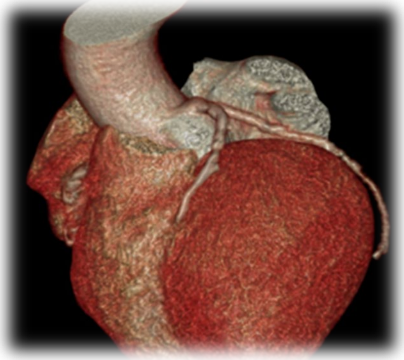
Coronary arteries can be assessed non-invasively by transthoracic or transesophageal ultrasound and magnetic resonance imaging computed tomography or computed tomography after endothelial-dependent vasodilation [33].

Transthoracic echocardiography is a classic method of evaluating cardiac function that, by its characteristics, can detect patients with a high cardiovascular risk, such as those with rheumatoid arthritis. Recent studies have demonstrated subclinical impairment of right and left ventricular function in patients with rheumatoid arthritis versus control, as demonstrated by the comparison of early ventricular (E-wave) filling, late ventricular (A-wave) filling, and the E/A ratio of the two lots [34]. A modern clinical application of transthoracic echocardiography is transthoracic stress echography with dipiridamol, able to evaluate the left coronary reserve. This represents the ratio of maximal coronary flow during stress to basal rate, which is a very sensitive diagnostic marker (> 90%) for coronary heart disease [35, 36]. In the literature, it has been reported that a value of coronary reserve flow <2 is associated with the presence of coronary stenosis [37]. In the absence of evidence of epicardial coronary stenosis, an abnormal coronary flow reserve may indicate a pathology of coronary microcirculation in patients with reperfused myocardial infarction, hypertension, diabetes mellitus, hyper-cholesterolemia, X syndrome or hypertrophic cardiomyopathy. Recent studies have also demonstrated a negative prognostic value of coronary reserve flow in patients with or suspected of coronary artery disease [38].

Transesophageal cardiac ultrasound is an investigation that can successfully complete transthoracic cardiac ultrasound, which has the disadvantage of visualizing the posterior structures of the heart, or which has the disadvantage of a difficult window of exploration in obese patients or affected by lung disease. Transesophageal cardiac ultrasound was used in a case-control study conducted on a group of 30 patients diagnosed with rheumatoid arthritis, which concluded that there was a high frequency of regurgitation of the mitral and aortic valves and obvious signs of cardiomyopathy in most patients [39].

Computer tomography is another method of assessing atherosclerosis present in the patient diagnosed with rheumatoid arthritis by completing the classical techniques mentioned above. A recent study aimed at examining the impact of rheumatoid arthritis on the prevalence and severity of coronary artery disease, concluded that the presence of coronary calcifications is common in patients with serum-positive rheumatoid arthritis [40]. This result was based on measurements of calcium score, an indicator of the degree of coronary artery calcification, by means of computer tomography. Figure 2 presents intense calcifications in the coronary artery walls, more evident on the LAD 2 (60-70%). The examination is non-invasive, without the use of a contrast substance, guided by the ECG; it does not require a long examination time and shows minimal irradiation.

Figure 2: Intense calcifications present in the coronary artery walls, more evident on the LAD 2 (60-70%). Normal detachment of coronary arteries.



The patient is lying down during the exam, and the calcium score is measured in deep inspiration. Coronary CT scan provides information on cardiovascular risk by calculating Agatston score: a small risk is equivalent to a score below 100 Agatston units, an intermediate risk of 100 to 300 Agatston units, and an increased risk of more than 300 Agatston units (Figure 3). The presence of an elevated risk score (over 300 Agatson units) requires a myocardial scintigraphy and the presence of a score of over 600 Agatson Units to perform invasive coronarography.

Still in the field of noninvasive imaging techniques, cardiac nuclear magnetic resonance is increasingly used, which is the gold standard for the evaluation of myocardial viability.

This modern technique was used in a study comparing the structure and function of myocardial patients with rheumatoid arthritis compared to a control group included in the multi-ethnic Baltimore study on atherosclerosis, unaffected by rheumatic pathology.

Figure 3: Cardiac CT: Calcium Scoring 529.74 Agaston units (LAD 329 UA, LCX 70.62 UA, RCA 129.86 UA)

	Scoring Results : Agatston Score Protocol			
	LAD	LCX	RCA	Total Coronaries
Score	329.26	70.62	129.86	529.74
#ROI's	11	6	7	24
AreaSq (sq.mm.)	113.36	30.46	45.97	189.8
Volume (cu.mm.)	283.41	76.16	114.93	474.5

The findings showed that there was no statistically significant difference between the two volumes in the left ventricular and telediastolic volumes, but that the left ventricular ejection fraction and the cardiac output were lower in patients with rheumatic arthritis, indicating a progression of heart failure [41]. Cardiac Magnetic Resonance has also been applied to a group of rheumatoid arthritis patients with no history of cardiovascular disease (pulmonary hypertension, coronary artery disease, valvulopathy, atrial fibrillation or diabetes), and the results were detection of subendocardial infusion defects in correlation with disease activity, respectively with markers of inflammation – PCR and VSH [42]. These results confirm the major involvement of inflammation in worsening cardiovascular status in patients with rheumatoid arthritis.

NON-INVASIVE IMAGING OF PERIPHERAL CIRCULATION

Peripheral circulation can be investigated non-invasively by a variety of methods from the classical ankle-arm index, or measuring post-occlusive reactive hyperemia with a plethysmograph up to brachial artery mediated vasodilatation, measured ultrasonographically or by magnetic resonance. These tests are useful in assessing endothelial function and may have considerable potential in the future in assessing rheumatic patients.

CONCLUSIONS

In conclusion, we can state that the modern investigation techniques allow identification of several subclinical stages of atherosclerosis, the interest in their early detection resulting from the observation that in this stage, through specific measures, the cardiovascular complications can be prevented.

Systemic chronic inflammation in atherosclerosis and rheumatic diseases brings to the forefront the need for a multibiomarker approach in cardiovascular risk assessment. Biological markers correlated with imaging tests may be important prognostic elements capable of delaying the progression of atherosclerosis, providing the opportunity for early cardiovascular treatment.

Until now, atherosclerosis imaging has been more centered on the anatomical aspect, with current trends focusing on a more functional approach using multi-modal images. The ultimate goal would be to fuse between anatomical and functional data and to achieve a more faithful image of the atherosclerotic plaque. In the future, an exploration of molecular and cellular mechanisms of cardiovascular disease is expected through molecular imaging that is able to overcome various aspects of inflammation involved in atherosclerosis. Slowing or stopping the progression of the inflammation process will be the future target of patient management by improving their prognosis and decrease the rate of their cardiovascular complications.

CLINICAL PRACTICE

Atypical case of achalasia

Andreea Grigore[1], Bianca Săndulescu[1], Alexandra Lulache[1], Andrada Popescu[1,2], Săndica Bucurică[1,2], Mihai Șotcan[1], Florina Vasilescu[1], Petruț Nuță[1], Mariana Jinga[1,2], Florentina Ioniță Radu[1,3], Daniel O. Costache[1], Raluca S. Costache[1,2]

INTRODUCTION

Esophageal cancer, represented by squamous carcinoma and adenocarcinoma, is ranked 8th in incidence among all the types of neoplasm in the world (456,000 new cases in 2012, 3.2% of total cancers), and is characterized by a significant lethal potential, being the 6th cause of cancer-induced mortality (400,000 in 2012, 4.9% of total cancers) [1]. 5 years survival after diagnosis is less than 5%, as esophageal cancer causes symptoms when more than 60% of the esophagus is infiltrated by tumor [2].

CASE REPORT

A 48-year-old patient presented for progressive dysphagia to solids, weight loss of about 15 kg and diffuse abdominal pain for the last 3 months. In addition, the patient noticed moderate dyspnea and intense pain localized at the right shoulder, without relation to movements. Two months before presentation, the patient performed a superior digestive endoscopy, which diagnosed him with ulcerative esophagitis, but without improvement of the symptoms despite recommended treatment. The patient is known with two surgical procedures, a Billroth I anastomosis for perforated gastric ulcer 12 years ago, and a cholecystectomy in 2018. Moreover, the patient had a stroke in 2014 and in 2015 was diagnosed with hepatic cirrhosis of unspecified etiology. The patient was a smoker with a 30 pack per year history and didn't work in a toxic environment.

The patient was underweight (BMI = 18.0 kg/m^2), but had a satisfactory overall condition. The abdomen was dense and painful on palpation.

The patient had hepatomegaly, was cardio-respiratory balanced and did not show any significant changes in the other organs and systems.

At the time of admission, stage diagnostics included dysphagic syndrome, abdominal algic syndrome, underweight, post-gastrectomy status, sequelae of stroke, liver cirrhosis in observation.

It is to be mentioned the inflammatory syndrome (fibrinogen = 484 mg/dL), cholestasis (total bilirubin = 1.47 mg/dL, direct bilirubin = 0.45 mg/dL, alkaline phosphatase = 145 U/L, GGT = 322 U/L), hyposideremia (Fe = 58 micrograms/dL) without anemia (Hb = 14.2 g/dL, Ht = 41.2%, RBC count 4.70 million/mm^3). During

hospitalization, hemoglobin, hematocrit, and RBC count decreased but did not indicate iron deficiency anemia (hemoglobin = 13.6 g/dL, hematocrit = 39.5, number of erythrocites = 4.5 million/mm^3). The patient's hormonal profile indicated euthyroidism. The patient was tested for HIV infection, hepatitis B and C virus infection, Kohn bacillus infection, but the results refuted those diagnostics. CEA and CA 19-9 had elevated values (CEA = 58.21 ng/mL, CA19-9 = 47.53 U/mL) and α-fetoprotein was slightly above the normal range (AFP = 1.1 ng/mL).

Abdominal ultrasound and thoracic radiography did not reveal pathological changes in the first phase. At upper digestive endoscopy fluid debris were present in the esophagus and stomach that prevented visualization of the digestive tract. At the repeated upper digestive endoscopy, white deposits were attached to the normal mucosa at the level of the esophagus, characteristic of mycotic esophagitis. Initially, we couldn’t overcome the cardia with the normal endoscope, which is why we turned to babyscope. There were no pathological changes in the stomach and duodenum I and II, and the mouth of anastomosis from the perforated ulcer surgery was supple. Due to these endoscopic findings, the patient underwent esophageal manometry, and was diagnosed with type 2 achalasia (panesophageal pressurization 100%, IRP = 80.2 mmHg).

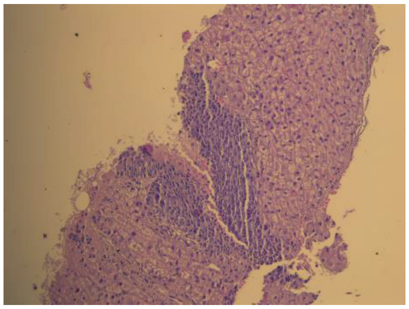
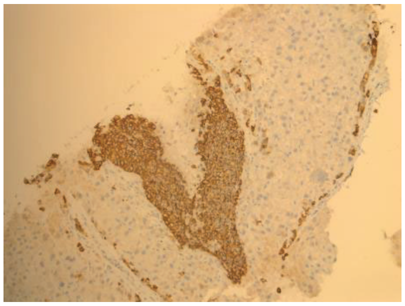
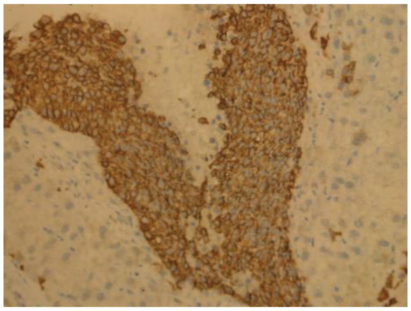
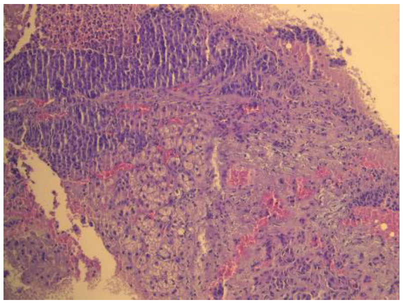
Taking into account the persistent symptoms and the changes of the above mentioned laboratory analyzes, computerized thoracic and abdominal tomography with contrast substance was performed. Computed tomography revealed pulmonary diffuse multiple micronodular lesions of millimetric dimension. At the eso-gastric junction a tumor block was described, with exophytic growth, with polylobate form and iodophyllic aspect, with a maximum diameter of about 5.5/3.8 cm, with small necrosis included, causing distension and stasis in the upstream esophagus. Additionally, adenopathy blocks in the small gastric curvature and celiac trunk were present, measuring up to 6 cm in diameter, the largest being without boundaries of demarcation with the celiac and pancreatic trunks. The liver was increased in size, with a maximum cranio-caudal diameter of 19.5 cm, with irregular contour, and irregular inhomogeneous structure due to the presence of multiple nodular lesions, randomly developed in the entire parenchyma that measured up to 1.8 cm, iodophyllic, some with a tendency to conflate, compatible with secondary lesions. Intrahepatic peripheral bile ducts in the left lobe exhibited slight dilation, most likely by infiltration generated by secondary lesions while extrahepatic bile ducts were unchanged. No pathological changes were detected in the abdominal vein circulation as well as in the spleen, pancreas, kidneys or adrenal glands.

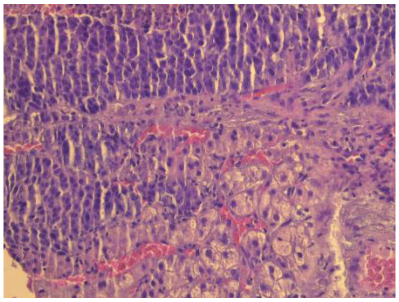
Concluding the tomographic examination, it showed that the patient had a esogastric junction tumor with bilateral pulmonary and hepatic metastasis and abdominal adenopathy. Later on, the oncological consult confirmed the suspicion of eso-gastric tumor with metastases and recommended biopsy of the hepatic nodules in order to perform the pathological anatomy and immunohistochemical examinations. Hepatic tissue fragments were thus obtained by ultrasound-guided biopsy puncture and the result were: small fragments of liver tissue with neoplastic infiltrates of poorly differentiated carcinoma which is arranged in nests of different sizes. Tumoral cells were cytokeratin7 positive and CDX2 positive. The immune-histochemistry and histopathologic aspects sustain the diagnosis of hepatic metastasis of poorly differentiated gastric adenocarcinoma.

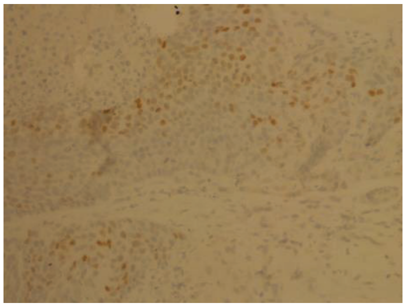












The patient was then referred to a thoracic surgical consult which stated that the tumor had no surgical indication and in the event of total dysphagia the therapeutic indication was to place an esophageal stent or a gastrostomy.

An esophageal stent was place and the patient remains under oncologic surveillence.

DISCUSSIONS

The differential diagnosis in this case started from dysphagia, the symptom which was the most intense and disturbing for patient. One type of dysphagia is the oropharyngeal dysphagia (diseases of the mouth, hypopharynx, esophagus above) in which case the cause can either be neuromuscular (SLA, central nervous system tumors, multiple sclerosis, myasthenia gravis) or structural (carcinoma, throat infections, Zenker's diverticulum) [3]. However, in this type of dysphagia, coughing and choking are described immediately after swallowing, the symptoms are often located precisely in the neck and in some cases food and fluids follow the path of the trachea or the nose. Another type of dysphagia is esophageal that can be caused by primary disorders of motility (achalasia, esophageal spasm, esophageal hypercontractility or other disorders of the peristalsis) or secondary disorders of motility (Chagas' disease, dysfunction of gastroesophageal reflux disease, scleroderma), or may be due to intrinsic structural pathologies (benign or malignant tumor, diverticulum, eosinophilic esophagitis, esophageal rings, foreign bodies, peptic stricture) or extrinsic ones (mediastinal tumors, osteophytes spinal, vascular compression) [3].

Considering the patient's features of the dysphagia, progressive dysphagia for solids accompanied by weight loss, there was an initial suspicion of a mechanical cause with a higher likelihood of malignant tumor formation. In general, peptic strictures caused by gastroesophageal reflux disease are accompanied by chronic heartburn and do not cause weight loss. The normal endoscopic examination of the esophageal mucosa initially directed the attention to a motility disorder, the most common being achalasia, a pathology characterized by poor relaxation of the lower esophageal sphincter in swallowing and lack of peristalsis in the smooth esophageal muscles. Dysphagia in this disease is progressive, occurs both for solid and liquid foods and is frequently associated with regurgitation, chest pain, weight loss symptoms that usually progress insidiously within about 2 years [4]. Although manometry diagnosed the patient with achalasia, the other symptoms, namely diffuse abdominal pain, dyspnea, and shoulder pain required the continuation of the investigations, the problem raised being if all the patient's symptoms were in the context of the same disease or another disease overlapping the esophageal pathology. From paraclinical examinations, elevated tumor markers have turned attention to a possible malignant tumoral pathology at the abdominal level that required CT examination, which was the one that brought the most important information to the case.

The particularity of this case is that although the patient was initially diagnosed with type II achalasia, the manometry examination showed pseudoachalasia in the context of esophageal cancer. Data from literature suggest that such presumptive results in any manometry examination are not specific to achalasia and under the conditions of sudden symptoms in less than 1 year, with a weight loss of more than 7 kg in a patient over 50, the suspicion of pseudoachalasia is raised. Thus, 5% of the manometric results indicating achalasia are actually given by tumor pseudoachalasia [5]. Such a case has been published by Segal et al, a case of a 50-year-old UK patient with the same symptomatology as the one of the patient in our center where the diagnostic process indicated achalasia in the first phase, but metastatic adenocarcinoma was eventually detected [6].

An interesting aspect to be mentioned is that the relationship between achalasia and cancer may be a causal one, which is already known in medical practice. Patients with achalasia are at risk of developing esophageal cancer, with the predominance of the squamous cell cancer and the adenocarcinoma in some situations. On one hand, achalasia causes esophageal stasis with bacterial overpopulation and production of various chemical compounds, while causing chronic inflammatory changes in the esophageal mucosa and dysplasia. Although this complication of achalasia is reduced in frequency, the prevalence of cancer in achalasia being variable according to several studies, there were several reported cases in literature [7]. Rios-Galvez et al published a case of a patient, known with achalasia for more de 15 years, whose symptomatology had significantly aggravated within 6 months and who, after following investigations, is diagnosed with squamous carcinoma of the esophagus [8]. What is different in our case is precisely the absence of the personal pathological history, achalasia requiring a prolonged period of illness for the esophageal malignancy to occur. On the other hand, esophageal adenocarcinoma occurs more frequently in the context of gastroesophageal reflux disease as a complication of the interventional treatment of achalasia by esophageal dilatation and myotomy [7].

CONCLUSION

In conclusion, dysphagia may occur in many benign or malignant conditions, but in a patient with alarming signs such as age, marked weight loss, even under the condition of a diagnosis of neuromuscular motility disorder, the suspicion of a malignant process must always be raised and we should act accordingly, following paraclinical investigations that can confirm or refute it.

Autologous versus synthesis materials used in the surgical closure of CSF leak

R. Hainăroșie[1,2], Irina Ioniță[1,2], Cătălina Pietroșanu[1,2], S. Pițuru[1], Mura Hainăroșie[1,2], V. Zainea[1,2]

Abstract: *The evolution of the endoscopic skull base surgery in the last ten years had led to the development of new surgical reconstructive techniques. In the endoscopic reconstructive surgery of the CSF leaks both synthesis and natural materials. The advancement of the endoscopic reconstructive surgery was closely linked with the production of new synthesis materials. The aim of the paper is to compare the efficacy of synthesis versus natural materials in the closure of CSF leaks and to point out certain rules of when and where to use a synthesis or natural material.*

INTRODUCTION

In the reconstructive surgery of the skull base, the surgeon can use both natural and synthesis materials.

The developments of the endoscopic surgery of the skull base had led to removing bigger tumors from high-risk areas that were not suitable for endoscopic surgical approach up to now. The endoscopic surgical approaches tend to replace the external approaches even in malignant tumors of the skull base in selected cases.

Because of that, the surgeon started to encounter more defects at the level of the skull base with or without CSF leaks.

New surgical reconstructive techniques started to be developed in close connection with the production of new surgical reconstructive materials and adhesives.[1]

The materials used in the reconstruction of the skull base defect can be divided in autologous tissue and synthesis reconstructive materials.

Autologous tissues that are used in the reconstructive skull base surgery are: fascia, cartilage, bone, fat, free mucosal grafts, vascularize flaps and free flaps with micro anastomosis.

Fat can be used to obliterate dead space or to plug a CSF leak.[1]

Fascia lata or fascia temporalis can be placed in an underlay technique between the dura and the skull base or overlay technique in the sinus cavities. Multilayered fascia lata was effective especially in the management of open cisterns or in cases of another type of high-pressure CSF leak.[2]

Bone or septal cartilage are placed in the underlying tech-

[2] "Prof. Dr. Dorin Hociotă" Institute of Phonoaudiology and Functional ENT surgery, Bucharest, Romania

nique and are used to support the larger reconstruction of the skull base.[3]

The free mucosal grafts can be used in the closure of small skull base defects with or without CSF leak.

The vascularized flaps can be used to reconstruct large defect with a high rate of success.

When loco regional vascularized flaps are not available, and we are dealing with large defects, we can use free flaps with micro anastomosis.[3]

Autologous tissue is popular because their availability, biocompatibility and does not involve a cost. We have to take into account the morbidity of the donor site and the additional time that it will be spent in the operating room. All the autologous materials can be harvest with minimal difficulty, and the harvesting process can be planned.[4,5]

One of the advantages of the autologous materials is the rapid incorporation in the surrounding tissue. Hoseman demonstrated that the free middle turbinate mucosa graft was fixed after six days and the re-epithelization had been seen microscopically after 12 days. The autologous grafts do not produce an important inflammatory response, an important quality for patients that do require follow up endoscopic or imagistic exam because unnecessary biopsies will be avoided.

Disadvantages of autologous grafts are the limited tissue availability, and the additional incision is created. The major complication is not reported, but the donor site can sometimes associate pain, minor complications and require additional healing time.

The synthesis materials use in the skull base surgery can be divided into two categories: acellular human dermis and engineered collagen products.

Acellular human dermis (Alloderm) is used in many anatomical areas in the head and neck surgery in the last ten years. Multiple layers reconstruction at the level of anterior and middle cranial fossa had proved to be effective. Studies have been shown a successful closure of the CSF leak in 90-100% of cases on the first attempt. Additional surgical harvesting time is not required. The material has to be soaked for ten minutes before use. The acellular human dermis is a low skink age material. Crusting may occur for about eight weeks. Some authors have raised the theoretical risk of transmitting prion-mediated diseases, despite the fact that the skin is not known to be a reservoir of infectious material as Creutzfeldt Jacob disease. A recent study has shown that in the USA more than two million patients had undergone reconstruction surgery using acellular dermis grafts without any case of infection.

The other category of synthesis materials are the engineered collagen products that are the result of advancement in bioengineering. Those type of products is collagen-rich sponges from the animal that were processed to remove all cells and antigens. The animal collagen matrix is chemically treated to induce a cross-linking among the collagen fibrils. The result is a porous matrix of collagen. Those products are designed to fully incorporate into native tissue using remodeling collagen technology with minimal surrounding tissue inflammatory response. Histopathologic studies have shown a fibroblast infiltration starting with four weeks after surgery a full incorporation in surrounding dura by 16 weeks after surgery.

Studies reported that the bigger the pore size it is (100 µm) the fastest incorporation we have. For matrixes with a pore size between 10-20 µm the fibroblast population started to grow after six months. In cases of small pore size (5 µm), no fibroblast migration was seen after six months from the surgical reconstruction. Severe inflation is rarely seen when using collagen-based products.

The skull base surgery also needs a rigid support in cases of important defects. Synthesis materials used for creating the rigid support are poly-methylmethacrylate, hydroxyapatite, titanium mesh or plates and polytetrafluoroethylene.

Methylmethacrylate products are easier to use comparing the hydroxyapatite products due to the faster hardening time (10 versus 30 minutes). Another important quality of the methyl-methacrylate is the ability to hardening in a wet field. Studies have shown that after using them in reconstructive surgery, both materials give a minimal inflammatory response.

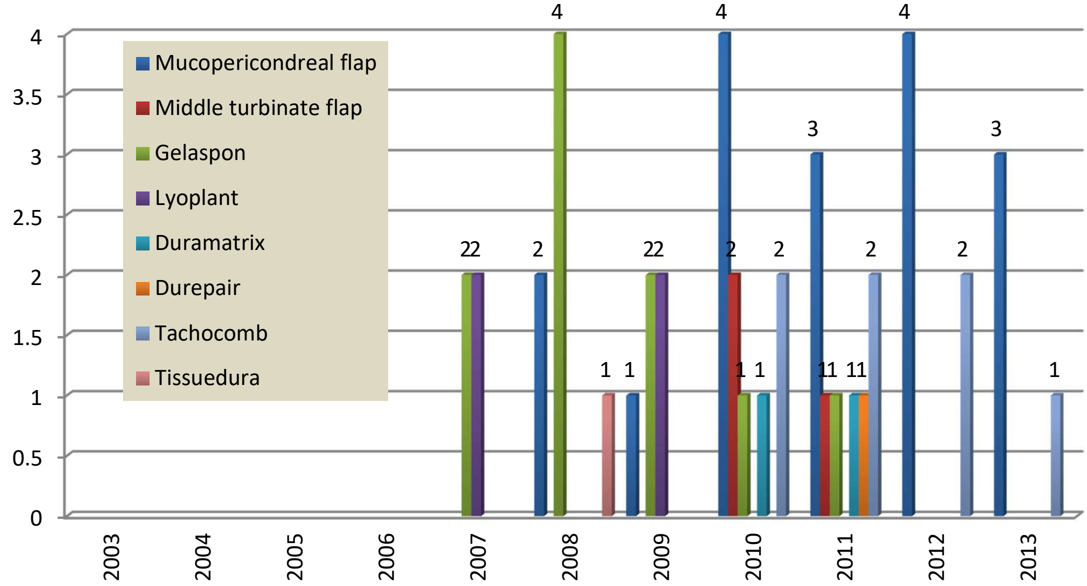
Titanium mesh and plates are malleable, are easy to see on imaging exams are quite safe to use in skull base reconstruction. Esposito found migration or dislodgement of the titanium mesh in 3 from 378 patients.

The surgeon must present the risk of a skull-base during dissecting the tumor and all the related risk to the procedure and the risks of not having the surgical treatment and the alternatives to the surgical treatment.

The surgeon is obliged to present to the patient all the reconstructive alternatives techniques, materials, biological glues used in the skull-base reconstruction.

Advantages, disadvantages, surgical risks and risks that occur if the reconstruction is not performed.

Table 1 – Synthesis and natural materials used in reconstructive surgery of the skull base in period 2003-2013



MATERIAL AND METHOD

We have used in our practice as synthesis materials collagen-based products. We have used starting with the year 2007 the following collagen products: Gelaspon, Lyoplant, Duramatrix, Durepair, Tachocomb, Tissuedura.

First, we have used those type of products to reconstruct small skull base defects with or without CSF leak in underlay and underlay technique. The important inflammatory response was not encountered. The results were good, and the primary closure of the CSF leak was 100%. The advantages of the synthesis products are the high availability, an important quantity of material availability and total integration in the host dura. The main disadvantage is the price of those products. We recommend using collagen-based materials in small skull base defects. When we are dealing with important defects of the skull the reconstruction using solely collagen-based product is not recommended, in that cases, the collagen products have to be used with vascularized intranasal or extra nasal flaps with rigid support.

RESULTS AND DISCUSSION

The natural materials that we have used in skull base reconstruction are fascia, cartilage, bone, fat, free mucosal grafts, vascularize flaps and free flaps with micro anastomosis. The main vascularized flaps that we have used are the mucoperichondrial septal flap described by Haddad and the middle turbinate flap.

CONCLUSION

We consider that naso-septal Haddad flap type to be the best option in skull base reconstruction due to its good vascular supply and versatility. The vascular supply of that flap is the septal branch of the sphenopalatine artery. We have never encountered necrosis of the flap even after radiotherapy. In case of recurrence the flap can be reused, it can be taken down, preform ablative surgery and reposition the flap. The surgeon can cover defects up to 25 cm^2. The surgeon will have a limitation in pediatric population up to 13 years due to the development of the nasal septum that can lead to the insufficient surface of the flap. The flap can include the mucosa from the nasal fossa floor; it can be prepared bilateral or contra-lateral.

Abstract: Aseptic bone necrosis (ABN), also known as avascular necrosis (AVN), is a serious and often overlooked complication of systemic lupus erythematosus (SLE), a chronic autoimmune disease with diverse symptoms. AVN in SLE is caused by multiple factors, including blood supply disruption due to clotting disorders, chronic inflammation, and especially prolonged use of moderate to high-dose corticosteroids. This review analyzes 17 out of 62 peer-reviewed European studies (2015–2024) from the PubMed database, focusing on osteonecrosis in lupus. AVN affects between 0.8% and 33% of SLE patients, with a mean symptomatic rate of 9%, while up to 29% may be asymptomatic. The femoral head is most commonly involved. Besides corticosteroid use, other risk factors include antiphospholipid antibodies (especially anticardiolipin IgM), endogenous hypercortisolemia, hypercoagulability, dyslipidemia, and active disease. In Romania, where no national registry exists, a representative case of a 27-year-old woman with undiagnosed SLE and bilateral femoral head necrosis without steroid exposure highlights the role of autoimmune coagulopathy. Misdiagnosis of her facial rash as rosacea delayed proper identification, emphasizing the importance of clinical awareness in atypical cases.

Keywords: osteonecrosis, automimmune disease, systemic erithematous lupus disease.

INTRODUCTION

Aseptic bone necrosis (ABN), also known as avascular necrosis (AVN), is a condition defined by the disruption of the bone's blood supply, leading to bone tissue death, in the absence of infection. It is among primary cause of disability in individuals diagnosed with systemic lupus erythematosus (SLE)[1,2].

Systemic lupus erythematosus is a prototypical connective tissue disorder of presumed autoimmune origin, exhibiting a broad spectrum of clinical manifestations, ranging from mucocutaneous involvement to life-threatening organ dysfunction[2].

Rheumatic diseases, in general, present either diagnostic challenges or management issues, and SLE is no exception. The complexity of SLE arises from two primary concerns: the diagnostic challenge posed by its diverse clinical presentations and the management difficulties associated with its multisystem involvement, compounded by a long list of complications related to both the disease itself and its treatment[3,4]. Due to the disease's aggressive nature and heterogeneous course, therapeutic interventions remain intensive, particularly in cases involving organ systems.

The complications of SLE stem not only from the disease pathophysiology but also from the treatment regimens. AVN represents a frequent complication in SLE, occurring in approximately 10–30% of patients, with the incidence depending on the clinical presentation[2,5]. AVN is a significant contributor to morbidity in lupus patients. The development of AVN in SLE is associated with various factors, including the use of corticosteroids, thromboembolic events, and potential vasculitis.

This manuscript is a review article focused on synthesizing current medical knowledge regarding aseptic bone necrosis in patients with systemic lupus erythematosus. The literature search was restricted to peer-reviewed publications.

The underlying hypothesis guiding this peer-reviewed literature analysis is that AVN in patients with SLE is not attributable to corticosteroid exposure, but rather results from a multifactorial pathophysiological process involving autoimmune-mediated endothelial dysfunction, prothrombotic states, and systemic inflammatory activity. Furthermore, it is hypothesized that a significant proportion of AVN cases may present prior to or concurrently with the diagnosis of SLE, thereby positioning osteonecrosis as a potential sentinel manifestation of an underlying undiagnosed autoimmune process. This review aims to elucidate these associations and patterns based on contemporary European evidence.

Materials and Methods

This review was conducted through a structured search of the PubMed biomedical database, targeting peer-reviewed literature published between January 2015 and March 2024. The search strategy included combinations of the following MeSH (Medical Subject Headings) terms and keywords: “systemic lupus erythematosus,” “avascular necrosis,” “aseptic bone necrosis,” “osteonecrosis,” and “Europe.” Only studies conducted on human subjects within European populations were included to maintain epidemiological and healthcare system comparability.

Inclusion criteria were:

- Peer-reviewed original research articles or systematic reviews;
- Studies involving patients diagnosed with SLE who developed avascular or aseptic bone necrosis;
- Publications between 2015–2024;
- Geographic focus limited to European cohorts.

Out of a total of 62 publications identified on the topic of osteonecrosis in the context of lupus, 17 studies were selected for in-depth analysis based on specific predefined variables, as described below.

Data were extracted and organized into a Microsoft Excel database. The following variables were evaluated: patient age and sex; timing of SLE diagnosis relative to AVN onset; osteonecrosis staging (where available); identified risk factors (corticosteroid use, antiphospholipid antibodies, hypercoagulability, dyslipidemia, hypercortisolemia); and diagnostic modalities used (MRI vs. conventional radiography). The aim was to synthesize consistent clinical patterns and identify the multifactorial contributors to AVN in the SLE population within the European context.

Statistical analyses were performed using both descriptive and inferential techniques.

Results and Discussion

This section presents the synthesized findings obtained from the systematic review. The results aim to elucidate clinical patterns, identify significant associations, and integrate the findings into the broader framework of rheumatological, orthopedic, and radiological practice across Europe. These insights are subsequently integrated into a critical discussion evaluating the implications for early detection, risk stratification, and clinical management of AVN in SLE patients.

SLE is a chronic autoimmune multisystem disease with variable incidence and prevalence across Europe (figure 1), which may reflect differences in genetic susceptibility, environmental exposures, healthcare accessibility, and diagnostic practices[6,7].

In Romania, epidemiological data remain limited;

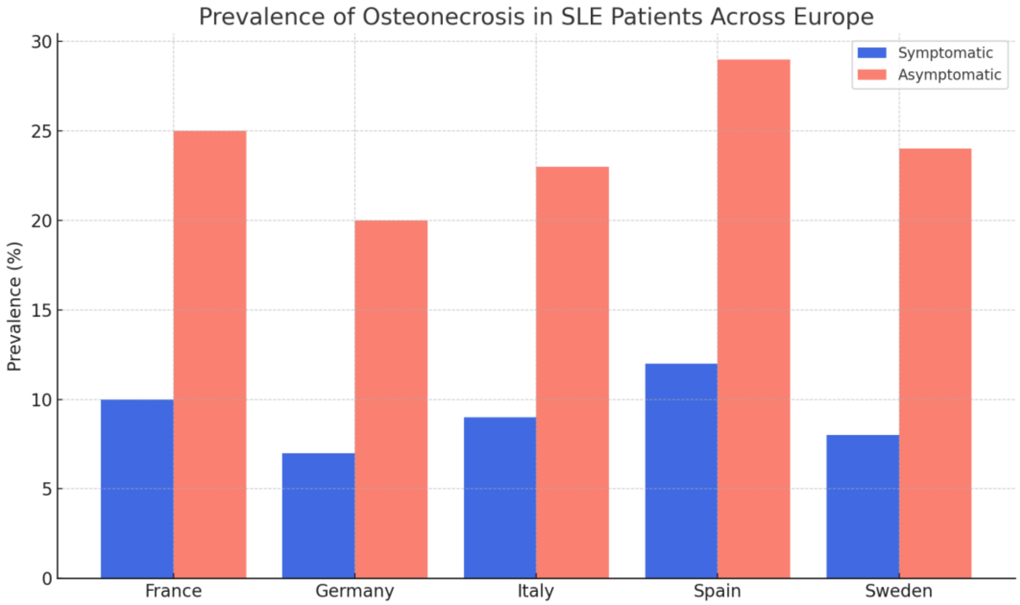

Fig.1- Prevalence of AVN in Europe

The above chart illustrates the prevalence of both symptomatic and asymptomatic aseptic bone necrosis among patients with systemic lupus erythematosus across five European countries. Notable inter-country variations are observed, with the highest prevalence reported in Spain (97/100,000 persons) and the lowest in Germany (36.7/100,000 persons)[7,8,9,11].

Based on the data from the reviewed literature, avascular necrosis in systemic lupus erythematosus exhibits a clear sex-related disparity. Approximately 85% of the reported cases occurred in female patients, reflecting the known female predominance of SLE itself. However, male patients with SLE appear to have a disproportionately higher risk of developing AVN relative to their representation in the general SLE population, suggesting a potential sex-related susceptibility to osteonecrotic complications[12,13,14,15,16,17].

The association between sex and the presence of AVN in SLE patients was assessed using the Chi-square test, appropriate for examining relationships between categorical variables. The analysis revealed a statistically significant association, indicating that although SLE predominantly affects women (~90%), male patients exhibit a disproportionately elevated risk of developing AVN relative to their population size within the SLE cohort (figure 2).

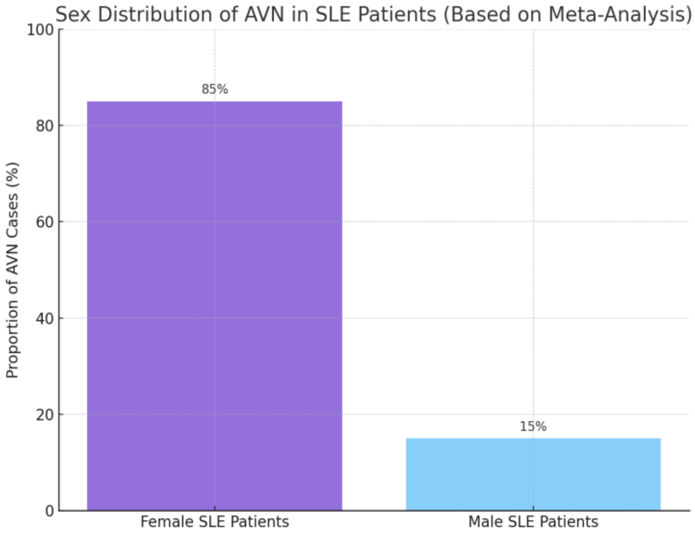

Fig.2 Sex Distribution of AVN in SLE patients

The age-related prevalence of AVN among SLE patients, is shown above (figure 3). The majority of AVN cases (52%) occurred in patients aged 20–40 years, reflecting the typical age of SLE onset and highest disease activity. This age group often coincides with early exposure to corticosteroids and aggressive immunosuppressive therapy, which may contribute to AVN risk.

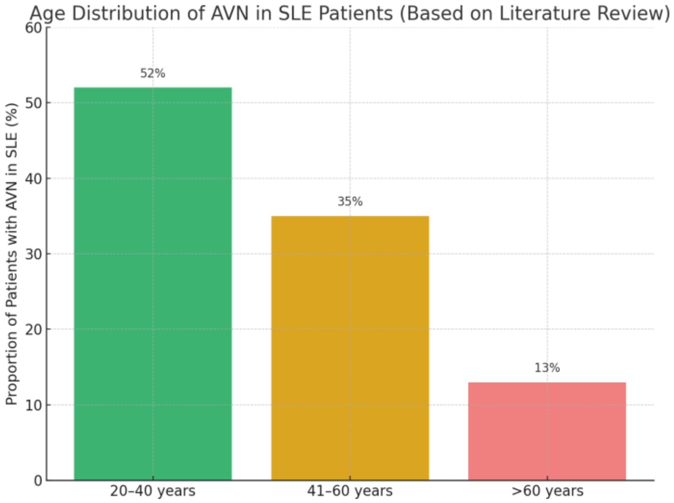

Fig. 3- Age distribution of AVN in SLE patients

A further 35% of cases were reported in the 41–60 years group, often associated with chronicity of disease, cumulative glucocorticoid burden, and vascular comorbidities. Only 13% of AVN cases were identified in patients over 60 years, likely reflecting both survivor bias and reduced use of high-dose steroids in elderly populations[11,12,13,14,16].

Based on the findings from the reviewed articles, the four most frequently reported anatomical sites of AVN in patients with SLE were as follows: Femoral head – 68% of cases (the most commonly affected site, due to its high susceptibility to ischemic injury and limited collateral blood supply), Knee (distal femur/proximal tibia) – 14% of cases (often associated with weight-bearing stress and microvascular compromise), Humeral head (shoulder) – 10% of cases (involvement tends to occur bilaterally and may be underdiagnosed due to subclinical presentation), Talus (ankle) – 5% of cases and the remaining 3% included other locations such as the jaw (mandible), vertebral bodies, and small bones of the wrist[7, 11,12,13,14,16].

These findings emphasize the need for focused imaging of high-risk joints, particularly in symptomatic or corticosteroid-exposed SLE patients.

According to synthesized data from the reviewed literature:

- 78% of patients had a confirmed diagnosis of SLE before the development of AVN, indicating that osteonecrosis is predominantly a complication of established disease, often related to corticosteroid exposure or disease-related coagulopathy.
- 22% of patients were diagnosed with SLE concurrently with AVN, suggesting that in some cases, osteonecrosis may serve as a sentinel clinical event, prompting further investigation that leads to the identification of underlying autoimmune pathology.

This emphasizes the importance of considering systemic autoimmune disorders such as SLE in the differential diagnosis of atraumatic osteonecrosis, particularly in young patients or those presenting with systemic signs[11,12,13,14,15,16,17].

Based on pooled data from the reviewed articles, the majority of systemic lupus erythematosus (SLE) patients diagnosed with AVN were identified in advanced radiologic stages (figure 4):

- Stage I: 10% (early, MRI-specific findings)
- Stage II: 20% (mild structural changes)
- Stage III: 35% (subchondral collapse)
- Stage IV: 35% (joint space narrowing, secondary osteoarthritis)

This distribution underscores the delayed detection of AVN in clinical practice, with over 70% diagnosed at stages III or IV—often beyond the window for joint-preserving interventions[11,17].

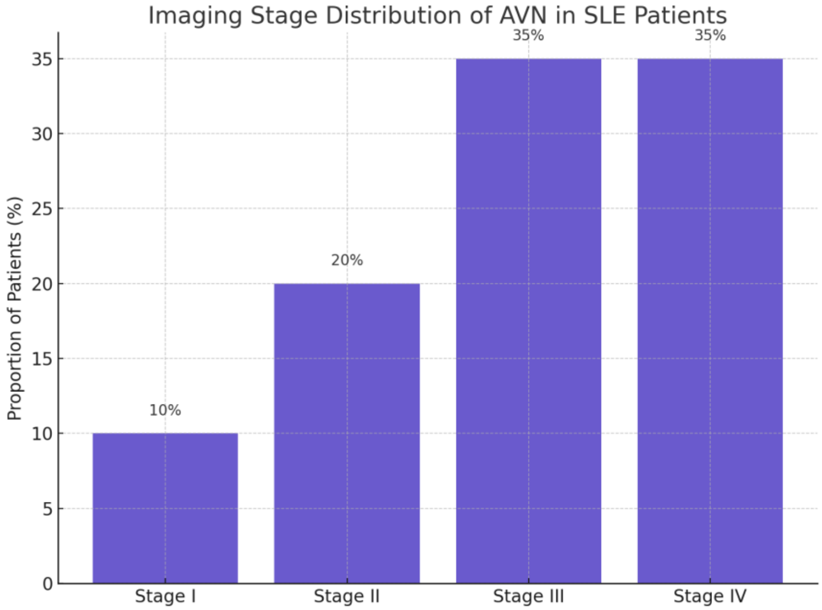

Fig. 4 – Imaging stage distribution of patients

Regarding the imaging modalities employed for diagnostic purposes, the following distribution was observed among the reviewed cases: 45% of patients were diagnosed using MRI alone, underscoring its superior sensitivity in detecting early-stage AVN prior to radiographic changes, 25% of cases relied exclusively on plain radiography (X-ray), despite its limited sensitivity in early-stage AVN and potential for false-negative results in the absence of structural alterations and 30% of patients underwent both MRI and X-ray, highlighting clinical awareness of radiographic limitations and the recognized diagnostic value of MRI as a complementary tool.

These findings (figure 5) emphasize the critical role of MRI in the early identification and accurate staging of AVN.

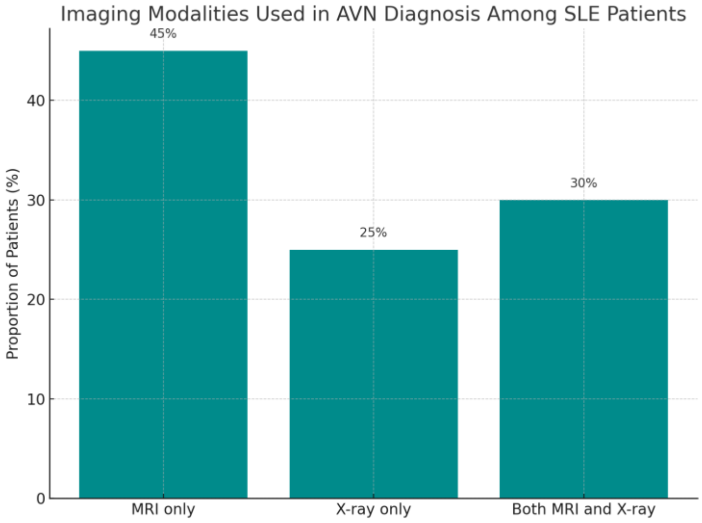

Figure 5- Imaging modalities used in AVN diagnosis among SLE patients

The distribution of key risk factors identified among patients with SLE who developed AVN, based on data synthesized is shown above (figure 6):

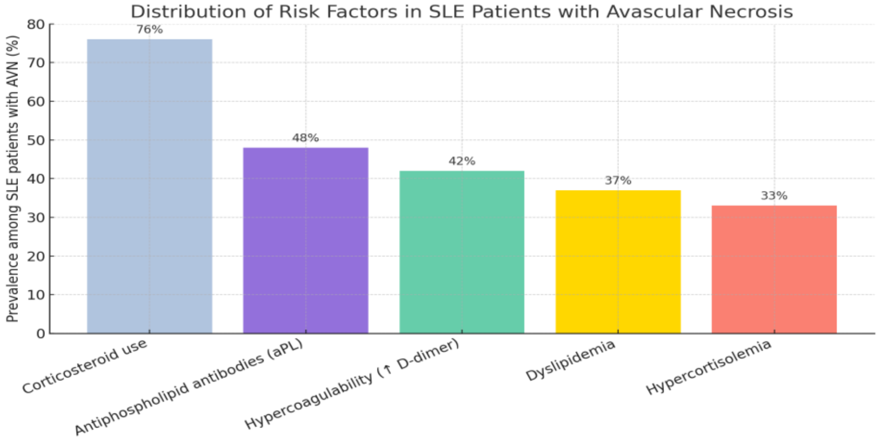

Fig. 6- Distribution of risks factors in SLE patients with AVN

The compiled data revealed the following distribution of risk factors:

- 76% of cases had a history of corticosteroid use, affirming its central role as the predominant modifiable risk factor for AVN.
- 48% demonstrated positivity for antiphospholipid antibodies (aPL), particularly anticardiolipin IgM, supporting the contribution of autoimmune-mediated vascular injury.
- 42% showed laboratory evidence of hypercoagulability, including elevated D-dimer levels, indicative of a prothrombotic state.
- 37% were reported with dyslipidemia, reflecting the vascular and metabolic burden in chronic autoimmune disease.
- 33% exhibited hypercortisolemia, either iatrogenic or endogenous.

These findings emphasize the multifactorial nature of AVN pathogenesis in SLE, warranting comprehensive risk stratification and early intervention strategies[7,10,11,12,13,15,17].

To explore the relationships between clinical variables associated with aseptic bone necrosis (ABN) in systemic lupus erythematosus (SLE), a Pearson correlation analysis was conducted (figure 7). The following continuous variables were selected based on their pathophysiological relevance and availability in the reviewed literature:

- Corticosteroid dose (mg/day)
- D-dimer level (μg/mL) as a marker of hypercoagulability
- Imaging-based AVN stage (1–4)

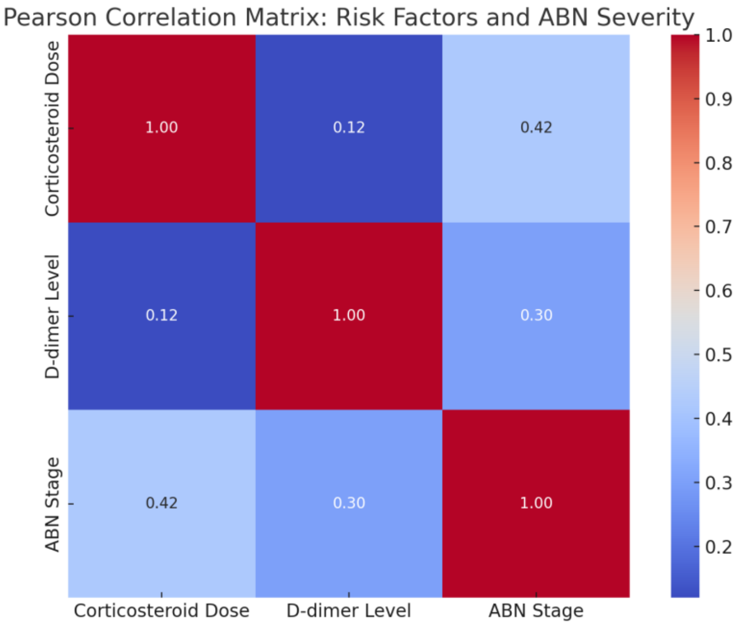

Figure 7-Pearson Correlation matrix between risks factors and ABN severity

A moderate positive correlation (r ≈ 0.42) was observed between corticosteroid dose and AVN stage, indicating that higher glucocorticoid exposure is associated with more advanced osteonecrotic changes.

A weak-to-moderate correlation (r ≈ 0.30) was noted between D-dimer levels and AVN stage, suggesting a potential link between thrombotic activity and disease severity.

Minimal correlation was found between corticosteroid dose and D-dimer levels (r ≈ 0.12), reflecting the multifactorial and potentially independent contributions of these variables.

These findings support the multifactorial pathogenesis of AVN in SLE and highlight the importance of integrating both inflammatory and thrombotic parameters in clinical risk assessment.

To assess whether a correlation exists between corticosteroid dosage and the imaging-defined stages of AVN, a One-Way ANOVA test was employed.

The boxplot presented above (figure 8) demonstrates the distribution of corticosteroid doses (mg/day) among three AVN stages in patients with SLE: Stage I, Stage II, and Stage III–IV.

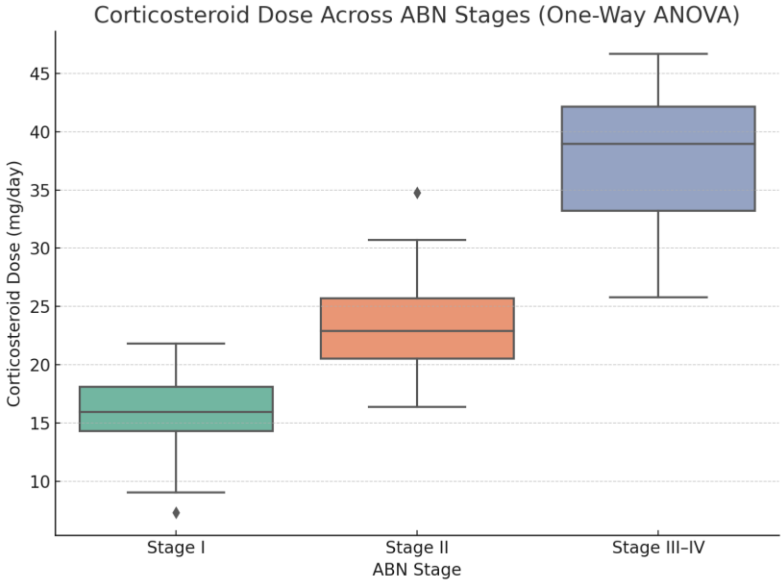

Fig. 8- Corticosteroid dose across ABN stages (one Way ANOVA test)

The ANOVA test produced a highly significant p-value (< 0.0001), confirming that the differences in corticosteroid exposure across the three groups are statistically significant.

These findings strongly support the hypothesis that greater cumulative corticosteroid use is associated with more advanced stages of osteonecrosis in patients with SLE.

In conclusion, the development of AVN in SLE patients reflects a multifactorial pathological process that extends beyond corticosteroid exposure. These findings underscore the necessity for a multidisciplinary approach—involving rheumatologists, radiologists, and orthopedic surgeons—to facilitate early detection, individualized risk stratification, and timely therapeutic intervention.

Following the comprehensive review of the European medical literature on AVN in SLE, we present a romanian clinical case in order to identify and explore potential parallels between the data reported in the literature and the findings observed in a real-life patient scenario.

ROMANIAN CASE REPORT:

The case is about a 27-year-old male patient who initially presented with osteonecrosis of the bilateral femoral head, in the context of previously undiagnosed systemic lupus erythematosus (SLE). The patient sought consultation due to persistent bilateral hip joint pain, which had been progressively worsening over the past month.

Medical History:

Approximately one year ago, he had been diagnosed with rosacea after presenting with erythema on the nasal pyramid and cheeks. The erythema was identified as a typical rash associated with rosacea, and he was treated with topical medications. However, the erythema did not resolve with the prescribed treatment, prompting further investigation. The patient had no significant past medical history beyond these episodes.

The patient denied alcohol consumption and was a non-smoker. He had not been on corticosteroids or any other medications prior to this event and had not taken any traditional or alternative medicine. Additionally, there was no significant family history of connective tissue diseases or other autoimmune disorders.

Orthopedic Consultation:

Upon presentation to the orthopedic department of our hospital, the patient described the bilateral hip pain as deep and localized primarily to the groin and gluteal regions. Initially intermittent, the pain had become progressively persistent, worsening with ambulation, prolonged standing, and stair climbing—raising suspicion of significant intra-articular pathology. He reported marked restriction in hip mobility, particularly during internal rotation and abduction, along with morning stiffness lasting more than 30 minutes, indicative of advanced joint involvement.

Physical examination revealed significant pain on passive hip mobilization, especially during flexion and internal rotation. Orthopedic provocative tests (FABER, log roll test) were positive bilaterally, further supporting the suspicion of intra-articular pathology.

The patient also reported occasional swelling in other joints, particularly in the wrists and knees.

The suspected diagnosis at presentation was: Osteonecrosis of bilateral femoral head, under etiological observation, as well as Facial erythema, which was also under etiological observation.

Paraclinical Investigations:

Laboratory Tests:

Routine laboratory tests were performed, which revealed mildly elevated inflammatory markers (moderately elevated erythrocyte sedimentation rate (ESR) of 78 mm in the first hour), hemoglobin level was 11.1 g/dL, and both her white blood cell count along with C-reactive protein, were within normal limits. She presented with thrombocytopenia, with a platelet count of less than 100,000/mmł, Low C3 and C4 levels (below 60 for C3 and below 15 for C4). The routine coagulation tests, including APTT, INR, and prothrombin time (Quick), were within normal limits and showed no abnormalities

Radiological Investigations:

The antero-posterior x-ray of the pelvis reveals bilateral femoral head involvment consistent with stage III (FICAT-Arlet) osteonecrosis, with loss of sphericity of both femoral heads, absence of femoral head collapse into the acetabulum, no significant joint space narrowing (figure 9).

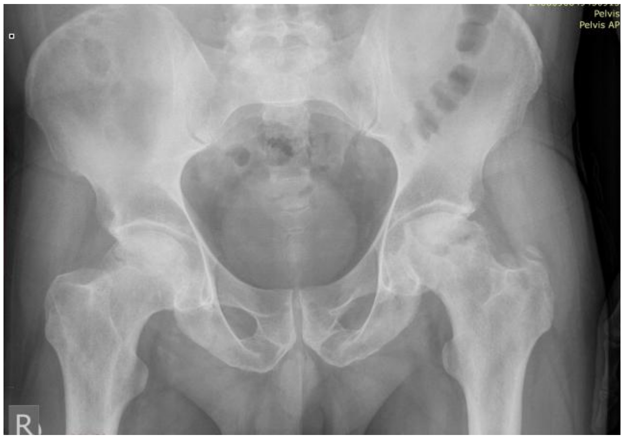

Fig.9 Hip X-ray

To further evaluate the extent of the lesion, an MRI of the hip was performed (figure 10a,10b, figure 11), which revealed characteristic findings of osteonecrosis of the both femoral heads, including areas of bone marrow edema and subchondral collapse.

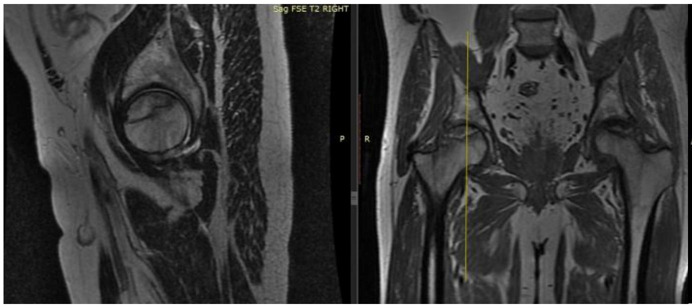

Fig. 10a- MRI of the right hip

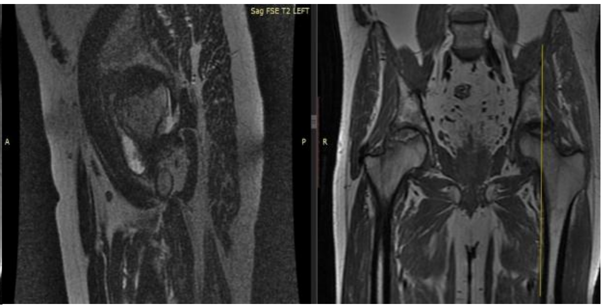

Fig. 10b - MRI of the left hip

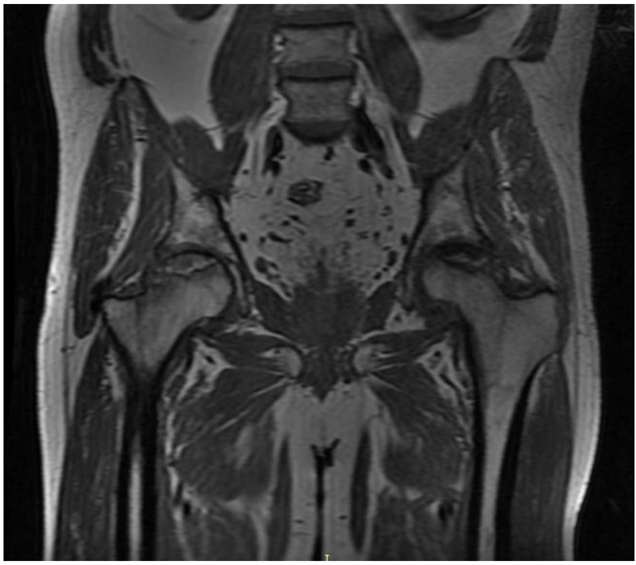

Fig 11. MRI of the hip

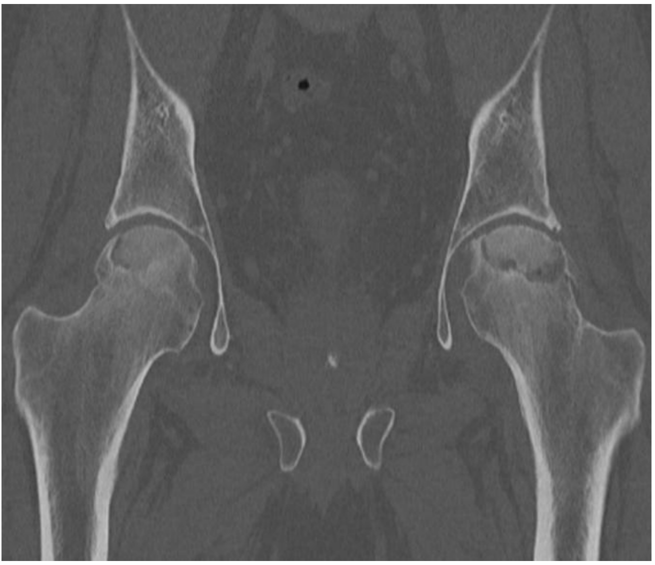

Fig.12 - CT scan of the hip

A CT scan of the hips was available from previous investigations performed by the patient, as shown above (figure 12):

Pelvic CT reveals bilateral femoral head osteonecrosis consistent with ARCO stage IIIA, characterized by collapse of the subchondral bone, loss of femoral head sphericity, and crescent sign of the hip joints.

To exclude other potential diagnoses and perform a differential diagnosis, several conditions were considered, including:

1. Infectious etiologies such as tuberculosis and chronic osteomyelitis.
2. Sickle cell disease due to its potential association with avascular necrosis.
3. Hypercoagulable states such as antiphospholipid syndrome, which may predispose to AVN.

4. Systemic vasculitis that could cause both joint involvement and AVN.
5. Rheumatoid arthritis with associated joint damage and systemic manifestations.
6. Other connective tissue diseases such as mixed connective tissue disease (MCTD) or dermatomyositis, which can present with musculoskeletal involvement.

As part of the diagnostic workup and given the elevated ESR and the presence of osteonecrosis lesions both dermatologic and rheumatologic consultations were sought, and additional tests were performed to further evaluate these differential diagnoses.

Dermatological Consultation:

Given the patient's positive history of erythema and the unusual persistence of the rash, a dermatology consult was requested. The dermatologic examination revealed a butterfly-shaped erythema over the cheeks and the bridge of the nose, a classic sign of systemic lupus erythematosus. In addition to the skin findings, the patient reported arthralgia with an inflammatory character, particularly in the wrists, knees, and shoulders. Based on these findings, the dermatologist suggested a referral to a rheumatologist for further evaluation of a possible autoimmune etiology.

Rheumatologic Evaluation:

Considering the clinical findings, including the butterfly-shaped erythema, a history of pregnancy loss, and joint involvement, the rheumatologist ordered further tests to assess for autoimmune disease. Additionally, the patient's coagulation profile showed a potential underlying thrombotic risk.

The following tests were conducted, and the results were as follows:

- Antinuclear antibody (ANA): Positive at a high titer of 1:1280, indicative of an autoimmune process.
- Anti-dsDNA (double-stranded DNA) antibodies: Positive at a titer of 120 IU/mL, confirming the diagnosis of systemic lupus erythematosus (SLE).
- Complement levels (C3, C4): Both C3 and C4 were significantly reduced, with C3 at 50 mg/dL (normal range: 90-180 mg/dL) and C4 at 10 mg/dL (normal range: 20-50 mg/dL), which is typical of active SLE.
- Anti-Sm (anti-Smith) antibodies: Positive at 25 U/mL, further supporting the diagnosis of lupus.
- Antiphospholipid antibody panel: Positive for both anticardiolipin antibodies (IgG) at 40 GPL U/mL (normal range: <10 GPL U/mL) and lupus anticoagulant, consistent with antiphospholipid syndrome (APS), which is frequently associated with SLE.

These results helped confirm the diagnosis of systemic lupus erythematosus with associated antiphospholipid syndrome.

Diagnosis:

The clinical presentation, laboratory findings, and positive autoimmune tests confirmed the diagnosis of Systemic lupus erythematosus with associated antiphospholipid syndrome (APS). The diagnosis of osteonecrosis of bilateral femoral head was also established as a complication of the underlying SLE, potentially exacerbated by the presence of antiphospholipid antibodies.

Treatment and Management:

The patient was started on hydroxychloroquine at a standard dose of 200 mg twice daily to manage the underlying lupus. Additionally, prednisone was initiated at a low dose of 10 mg per day to control systemic inflammation and prevent further disease progression.

Given the presence of antiphospholipid antibodies and the history of pregnancy loss, antiplatelet drug was prescribed at a dose of 75 mg daily to reduce the risk of thrombosis. As the patient tested positive for lupus anticoagulant, cumarin anticoagulant (Trombostop) was considered for anticoagulation therapy, with an initial dose of 4 mg daily, adjusted according to the patient's INR to maintain a therapeutic range of 2.0–3.0.

The patient was referred to orthopedic surgery for definitive management of bilateral femoral head osteonecrosis and underwent staged total hip arthroplasty procedures (figure 13).

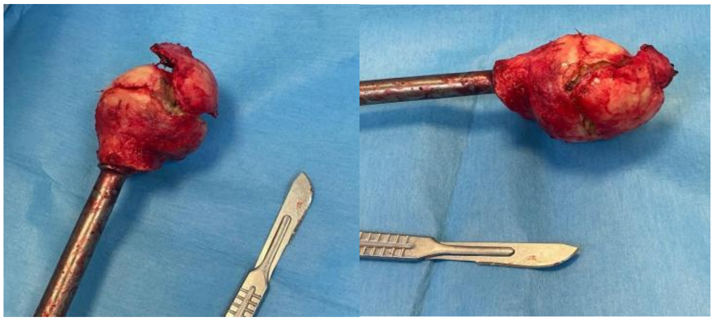

Fig 13. Intraoperative imaging of femoral head

Postoperatively pelvic x-ray demonstrates satisfactory positioning and alignment of bilateral total hip prostheses, with no immediate complications identified (figure 14).

The patient was also was referred to a structured physiotherapy program for postoperative rehabilitation.

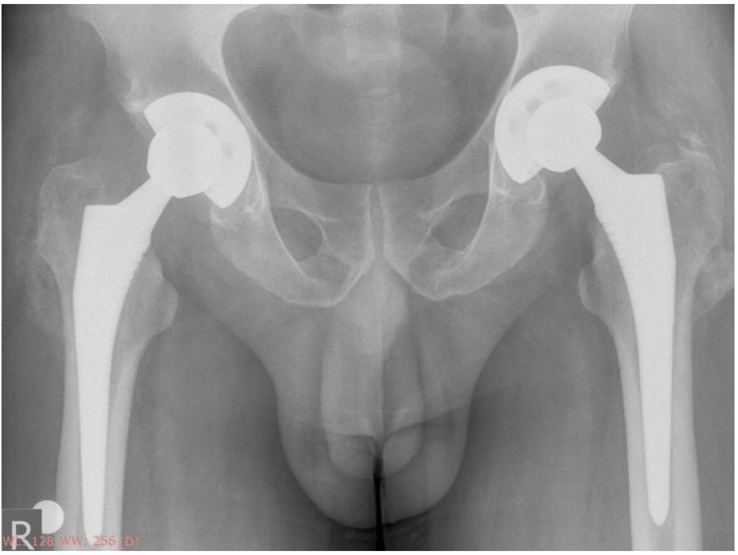

Fig. 14 Postoperative X-ray of the hip

Follow-up and Outcome:

The patient is currently being followed up regularly in both the rheumatology and orthopedic clinics. Her lupus symptoms are under control with the current treatment regimen, and she reports significant improvement in her joint pain.

At the six-month postoperative follow-up, the patient demonstrated significant functional recovery, with restoration of full range of motion in both hip joints and only minimal residual pain during high-demand activities.

The patient is also being monitored for any potential long-term complications related to the use of corticosteroids, such as bone density loss.

CONCLUSIONS:

This case highlights the importance of considering systemic lupus erythematosus in the differential diagnosis of young patients presenting with unexplained osteonecrosis, particularly when accompanied by characteristic dermatologic signs and autoimmune findings. Early diagnosis and appropriate management of SLE and associated complications, such as aseptic necrosis and antiphospholipid syndrome, are crucial to improving patient outcomes and preventing further morbidity.

The uniqueness of this case lies in the fact that the patient's presentation began with bilateral femoral head osteonecrosis, which was the first manifestation of the disease. The diagnosis of SLE was made later, after the development of osteonecrosis. The delay in diagnosis, compounded by an incorrect dermatologic diagnosis, led to the inability to initiate early treatment, which is crucial for better prognosis in autoimmune diseases like SLE.

This case underscores also the necessity of close collaboration between dermatologists, rheumatologists, and orthopedic specialists.

ORIGINAL ARTICLE

Basosquamous carcinoma: an overview of actual protocol and the importance of basal and squamoid components

Anamaria Grigore[1,2], Ana-Maria Oproiu[1,2], Mariana Costache[2,3], Oana M. Patrascu[2,3], Adrian Dumitru[2,3], Mihaela I. Zaharia[1], Alexandru Adrian[1,2], Constantin Condrea[1], Ioan P. Florescu[2]

Abstract: *Due to its scarcity, the basosquamous carcinoma represents a challenging pathology both as a result of its aggressiveness and potential of relapse and metastases, and also due to unclear management guides. Encountered under the name of basal cell carcinoma or metatypical carcinoma, the pathophysiology of such tumors is still unclear and it is not known yet if it either derives from a basal cell carcinoma or it could be a variant of transition to a squamous cell carcinoma.*

Due to low incidence, unclear treatment protocols and not enough research regarding squamous component in the aggressivity of basosquamous carcinoma, the aim of this paper is to analyze histopathological features of 5 cases of basosquamous carcinoma from Plastic Surgery Department of Emergency University Hospital, Bucharest, and correlate them with current literature.

Keywords: *basosquamous, metatypical carcinoma, squamous cell carcinoma, basal cell carcinoma*

INTRODUCTION

Although medicine is constantly evolving with new lines of diagnostic and treatment, skin cancer is a global problem with increasing occurrence and morbidity [1], entailing high costs for the health system [2].

First presented in 1910 by MacCormac, the basosquamous carcinoma is a rare pathology, with an incidence of approximately 1.2-2.7% of skin neoplasms [3,4]. Some of the risk factors identified are exposure to UV radiations, smoking and old age. Most frequently, this pathology is encountered on sun-exposed areas in Caucasian men.

Considered by some authors as a subtype of basal cell carcinoma or a rare version of it, the tumor presents characteristics of both basal and squamous cell carcinomas [5], and it is characterized by its risk of relapsing and remote dissemination [6].

Since the literature described them poorly and the treatment protocol is still unclear, the purpose of this paper is to present features of basosquamous carcinoma of a mini cohort from Plastic Surgery Department of Emergency University Hospital of Bucharest, diagnosticated during 2 months' period, showing the need of an optimized protocol as a different entity from basal or squamous cell carcinoma, and also showing the potential of increasing this pathology.

MATERIALS AND METHODS

The inclusion criteria were patients diagnosticated with basosquamous carcinoma from Plastic Surgery Department of Emergency University Hospital, Bucharest, during October-December 2019.

The study ran with the agreement of the ethics committee and the consent of the patients. All the patients underwent surgical excision after blood tests and the approval of the anesthetist. Preoperatively, imaging investigations were decided depending of the macroscopical features of the tumor (size, location, the adherence of surrounding tissue) and presence of adenopathies.

The diagnostic was provided based on histopathological examination, after surgical excision.

All tissue samples were fixed in 10% buffered formaldehyde and processed by conventional histopathological methods, with inclusion in paraffin and Hematoxylin-Eosin (HE) staining. Immuno-histochemistry was performed for one patient to identify the particularities of basosquamous carcinoma using CD10 (Figure 1), P53 (Figure 2), epithelial adhesion molecule (Figure 3), P63 (Figure 4), androgen receptor (Figure 5) and epithelial membrane antigen (Figure 6) antibodies provided by Biocare.

The indirect tristadial Avidin-Biotin complex method was used. The sections were deparaffinased in toluene and alcohol successive baths, rehydrated in alcohol baths with increasing concentrations, washed in phosphate saline buffer and incubated with primary antibody overnight.

Next, they were washed in carbonate buffer and developed in 3,3'-diaminobenzidine hydrochloride/hydrogen peroxide nuclear counterstaining with Mayer's Hematoxylin.

Also, all the patients enrolled were sent to oncological service after they were diagnosticated.

Figure 1: Basosquamous carcinoma: the tumor cell are negative for CD10 compared to most cases of basal cell carcinoma that are positive for this immunomarker, anti-CD10 antibody, 100x

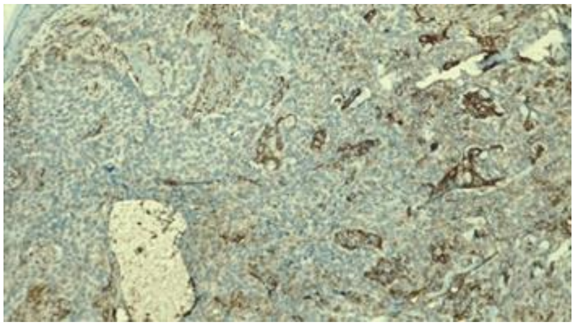

Figure 2: Basosquamous carcinoma: strong, diffuse nuclear immunoreactivity for P53 (hyperexpresion, mutant staining pattern). The expression pattern is similar to that found in squamous cell carcinomas of the skin, anti-P53 antibody, 100x

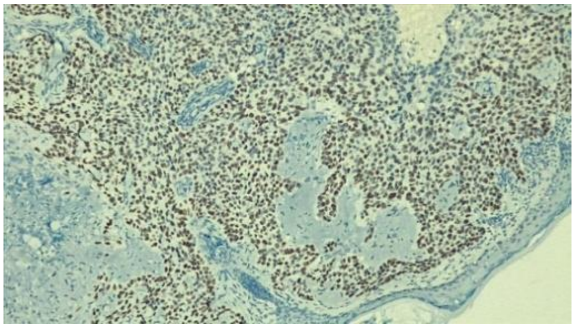

Figure 3: Basosquamous carcinoma: EP-CAM (epithelial adhesion molecule) negative in squamous component and positive in basal cell carcinoma (anti-EP-CAM antibody, 100x)

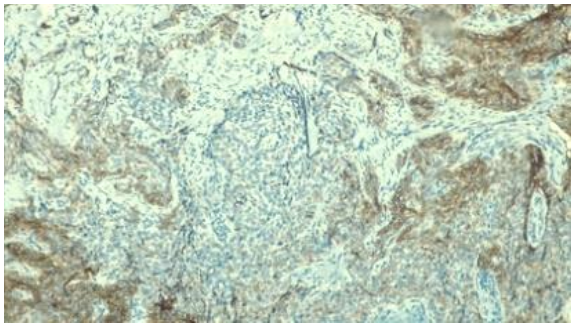

Figure 4: Basosquamous carcinoma: Positive P63 immunohistochemical reaction for both basal and squamous areas, anti-P63 antibody, 100x

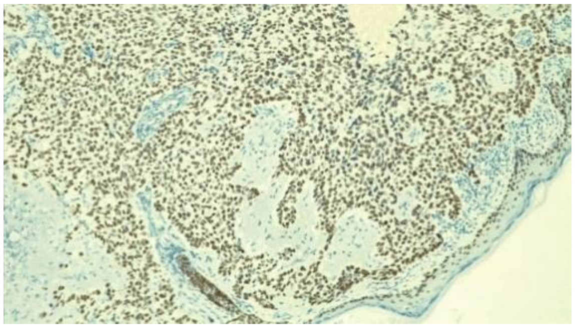

Figure 5: Basosquamous carcinoma: the tumor cell are negative for AR (androgen receptor), anti-AR antibody, 100x

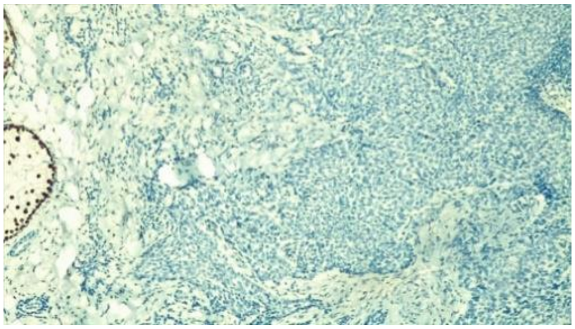

Figure 6: Basosquamous carcinoma: the tumor cells are EMA (epithelial membrane antigen) negative. Note the internal positive control (pilosebaceous unit), anti-EMA antibody, 100x

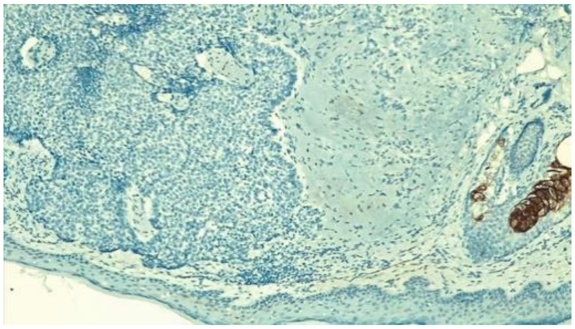


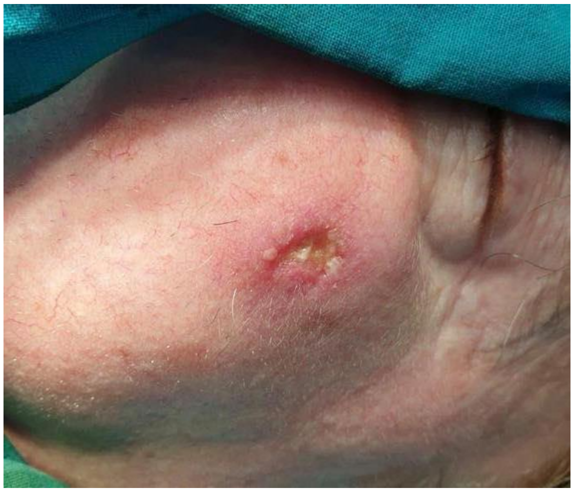
Case no. 1

The first case is a 75 years old man, with long term exposure to sun, who came to plastic surgery service with a growth of an endophytic tumor mass (Figure 7) on superior level of the left cheek measuring approximately 2/1.5 cm.

The tumor appeared about 3 months ago; it was ulcerated and presented perilesional telangiectasias which are a characteristic sign for basal cell carcinoma [7].

Considering the aggressiveness of the tumor and its evolution, surgical excision with pathology examination was decided.

Figure 7: Ulcerated endophytic tumor on superior level of the left check with perilesional telangiectasias, a characteristic sign for basal cell carcinoma



The histopathological examination (Figures 8 and 9) revealed an ulcerated tumor consisting of a superficial proliferation of malignant basal cell-type with basophilic cytoplasm and hypercromatic nuclei, with minimal atypia admixed with cells that have acidophilic cytoplasm, vesicular nucleoli and atypical mitoses infiltrating the deeper levels of the dermis.

The tumoral proliferation is surrounded by a lymphocytic inflammatory infiltrate.

Thus, a diagnosis of basosquamous carcinoma, with squamous predominance of 80% was made. The tumor infiltrated the deep dermis and was reported with a Clark index of IV, with perineural invasion >0.1 mm but without vascular invasion.

The tumor was completely excised.

Figure 8: Metatypical carcinoma, with solid nests of malignant cells with eosinophilic cytoplasm and vesicular nuclei, HE 10x

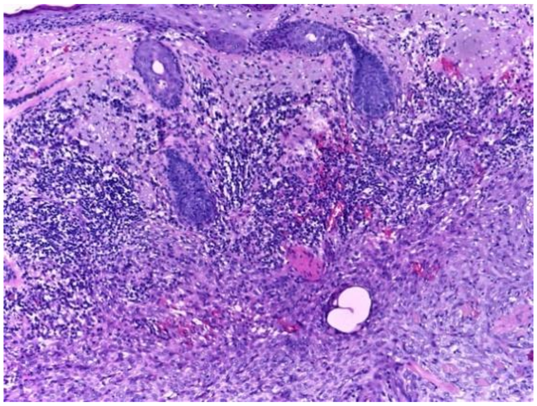


Figure 9: Basosquamous carcinoma with non-keratinizing squamous component of 80%, with solid and infiltrative pattern, reaching a nervous structure, HE 20x

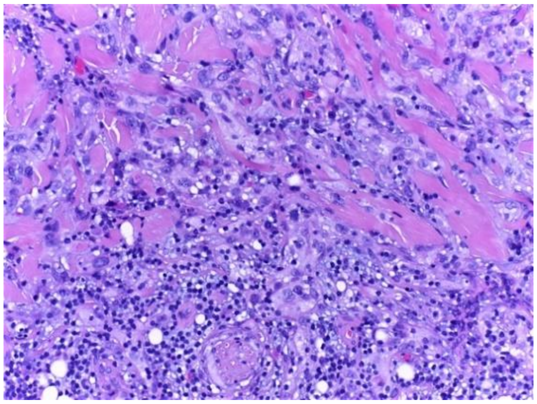
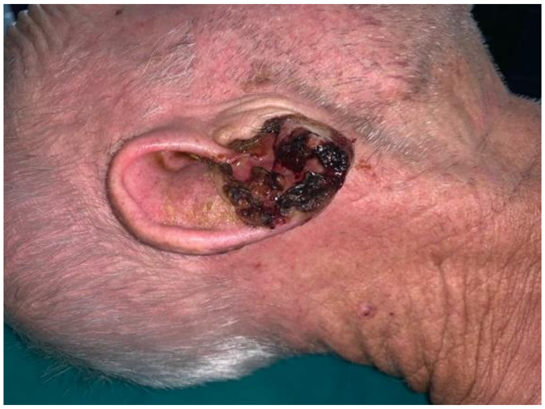


Case no 2

An 88-year old patient, former smoker, with long-term exposure to sun, presented with an ulcerated tumor located on the right auricular pavilion (Figure 10), covered with hemorrhagic crusts, measuring about 5/4 cm that appeared a few months ago. He came to our service because of local pain and tumor bleeding.

Figure 10: Ulcerated tumor on auricular pavilion



A preop cervical CT scan revealed multiple ganglia images at the superficial and deep laterocervical level, and also at the submandibular level, with the maximum size of 1 cm. The patient was also evaluated by the maxillo-facial surgery service, which recommended only the follow-up of those adenopathies. In this case, it was decided the partial amputation of the ear (Figure 11) with macroscopically tumor-free margins and reconstruction by fixing helix on auricular lobe (Figure 12).

Figure 11: Partial amputation of the ear

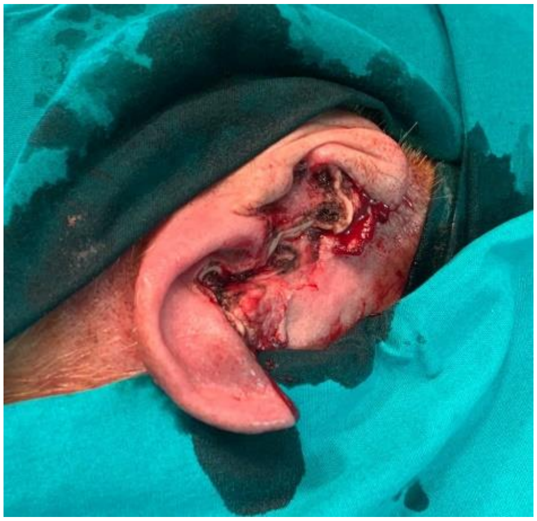


Figure 12: Day 3 postoperatively. Reconstruction of auricular pavilion

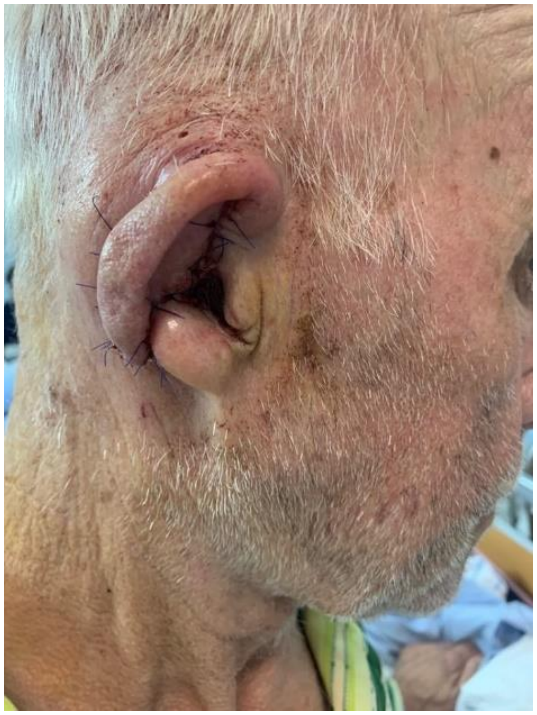

After conventional HE method processing and examination, a malignant proliferation of cells with intermediate aspects of both basal and squamous features was identified. The nuclei presented atypical mitoses, a hypercromatic and slighty oval nuclei. The solid proliferation infiltrated the soft tissue, and presented clear ulceration on the skin. A diagnosis of basosquamous carcinoma without cartilage infiltration was made. (Figures 13 and 14).

Figure 13: Ulcerated metatypical, invasive carcinoma, with a solid, non-keratinizing pattern, with intermediate aspects between basal and squamous cell; notice hyaline cartilage without tumor invasion, HE, 4x

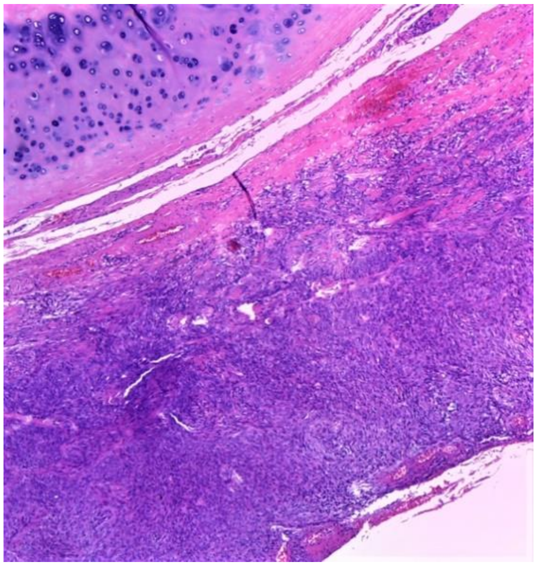

Figure 14: Ulcerated metatypical, invasive carcinoma, with solid islands of malignant cells, with hypercromatic nuclei and moderate pleomorphism, HE, 10x

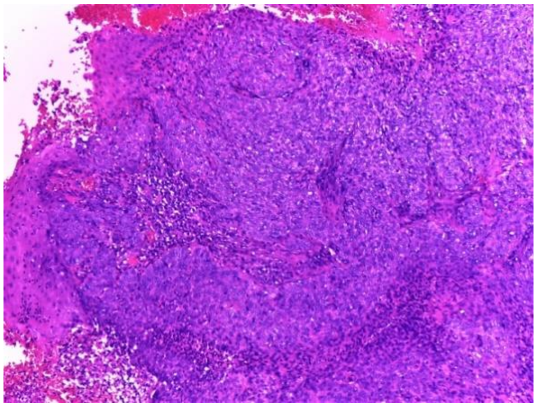
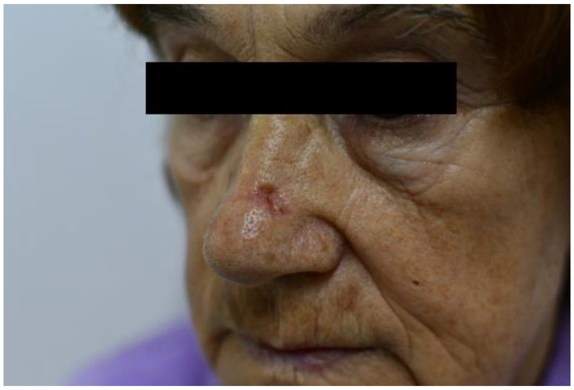


Case no 3

The 3rd case is of a 76 years old Caucasian woman who was transferred to plastic surgery service for a biopsy of a nasal pyramid mass (Figure 15). Her tumor appeared a few months ago after local trauma and sun exposure.

Figure 15: Ulcerated tumor of the nasal pyramid



[redacted]

After the resection, the histopathological examination revealed a metatypical carcinoma consisting of a proliferation of intermediate cells invading the dermis, incompletely excised (Figure 16). The re-excision revealed a small island of basaloid cell proliferation and an important granulomatous foreign body reaction with multinucleated giant cell reaction (Figures 17 and 18). Surgical margins were tumor-free.

Figure 16: Island of metatypical carcinoma invasive in dermis, HE 10x

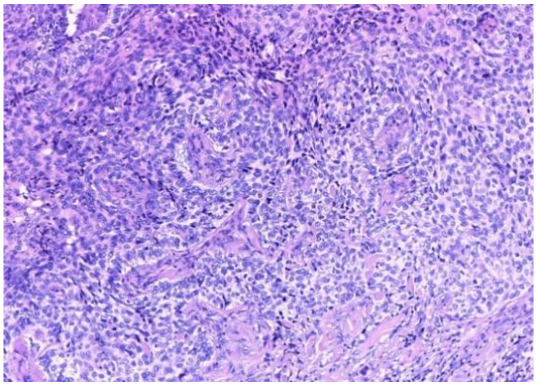


Figure 17: Re-excision of basosquamous carcinoma (granulomatous foreign body reaction with multinucleate giant cells, HE. 10x)

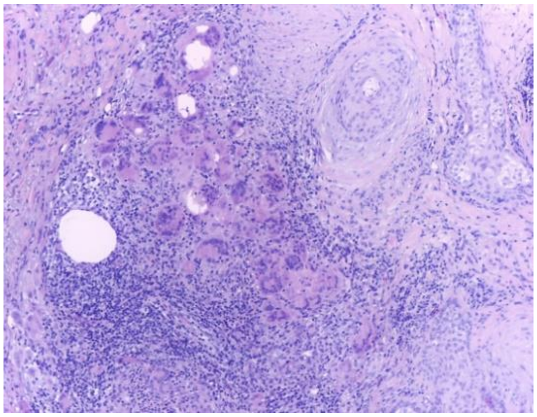

Figure 18: Re-excision of basosquamous carcinoma – isle of superficial basal cell carcinoma, HE, 10x

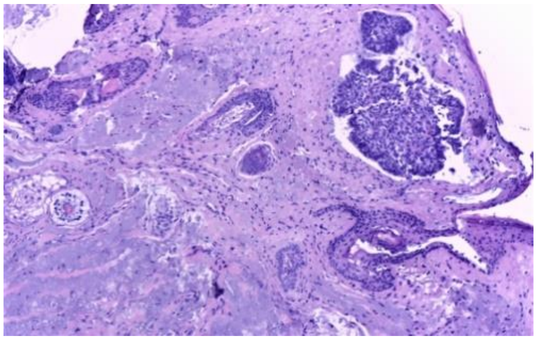
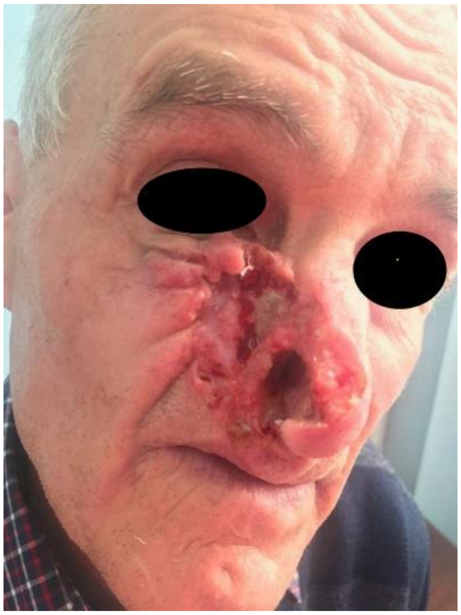


Case no. 4

The 4th case was a surgical challenge; the patient was a 68year old man, from rural environment, with an ulcerated giant tumor (Figure 19) on right nasogenian, malar and lower lid region, with an evolution of approximately 10 years. The dimension reached approximately 7.5/4 cm.

Figure 19: Ulcerated tumor covering the right nasogenian, malar and infraorbital area



[redacted]
[redacted]

Preoperatively, a cerebral-cervical-thorax CT scan to evaluate the degree of invasion of tumor and potential disseminations was performed, which revealed no local bone invasion and multiple multiple ganglia images, under 1 cm, at the level of mediastinal, axillar, submandibular and on bilateral carotid space.

The tumor was excised with macroscopically oncological safety margins. The defect remained needed cover with 2 local flaps, one right cervico-facial and one transposed frontal (Figures 20 and 21).

Figure 20: The defect after tumor resection

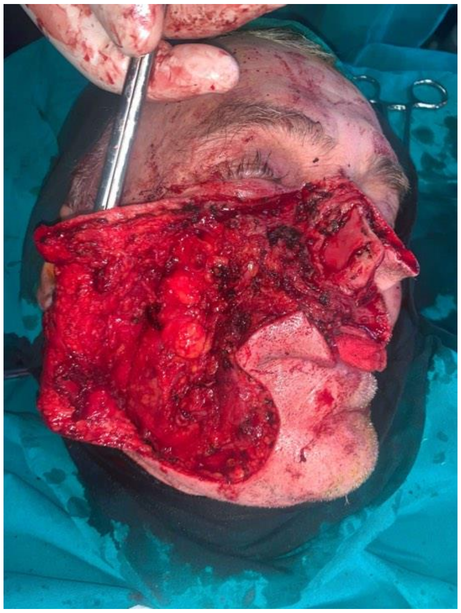


Figure 21: Three months post-surgery

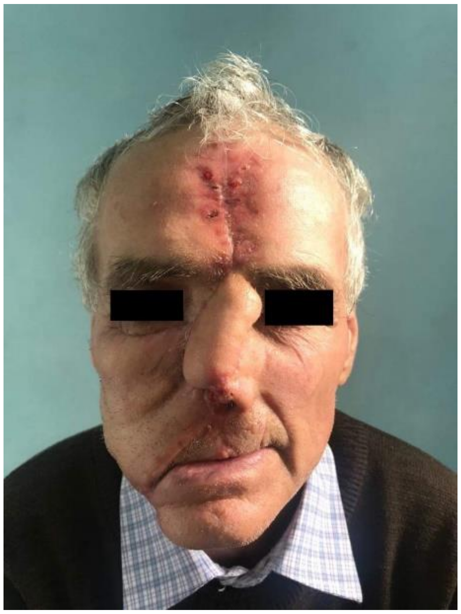

The histopathological exam confirmed the diagnostic of basosquamous carcinoma with a proliferation of intermediate and squamous cells with slightly spindle shape, with eosinophilic cytoplasm, infiltrating the deeper portions of the skin and ulcerating the epidermis (Figures 22 and 23).

The squamous component presented individual keratinization, with vesicular nucleoli and numerous atypical mitoses (Figure 24).

Figure 22: Basosquamous carcinoma (left side of photo) and respirator epithelium (right side of photo), notice the solid proliferation of intermediate cells with slighty spindle shape, with hypercromatic nuclei admixed with vesicular nuclei and eosinophilic cytoplasm, HE, 20x

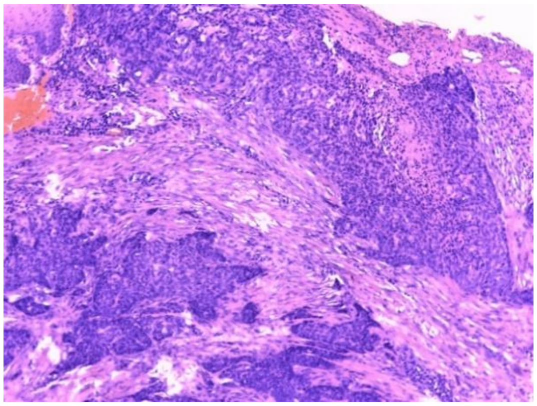

Figure 24: Detail of basosquamous carcinoma (squamous component) with individual keratinizing and several atypia, with pleomorphic vesicular nuclei, HE, 40x

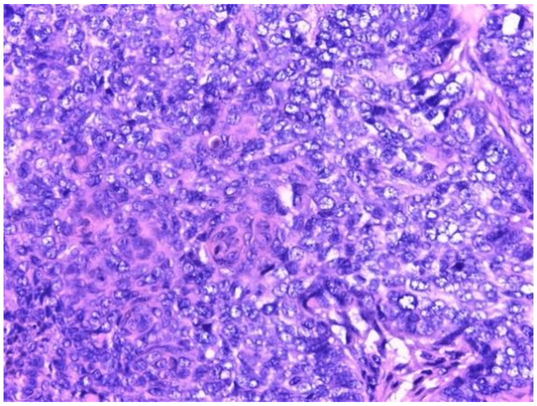
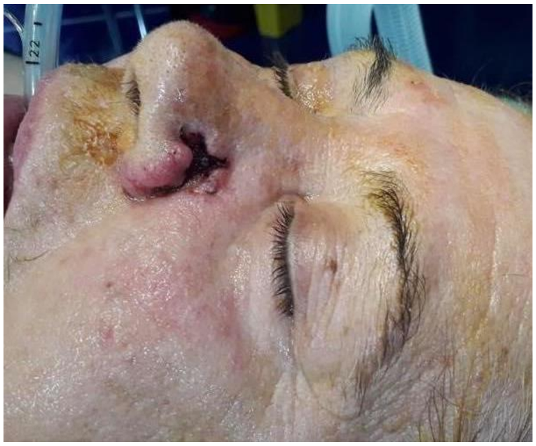


Case no 5

The last case is of a 76 years old woman, with insulin-dependent diabetes mellitus and obesity that presented with an ulcerated tumor (Figure 25) of approximately 2/2cm on the left nasal side.

Figure 25: Erosive tumor on left nasal side



The tumor progressed to a full thickness skin erosion over a 2 years time period. The surgical excision skin defect (Figure 26) was covered with a local flap (Figure 27).

Figure 26: Defect remained after tumor excision

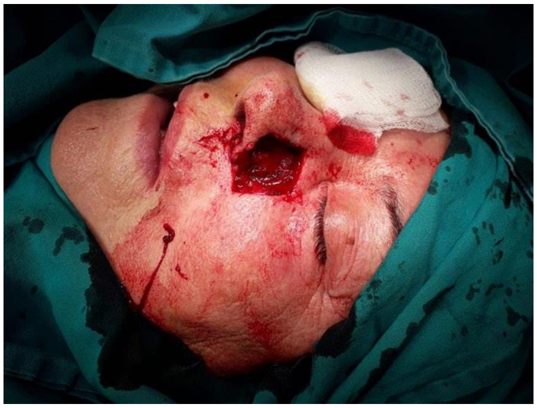


Figure 27: Immediately post-surgery, cover of defect by rotated nasolabial flap

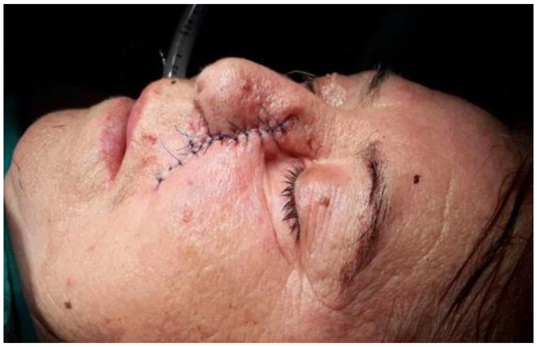

The pathology results under Hematoxilin-eosin examination revealed a malignant proliferation of polygonal squamous cells with polymorphism and eosinophil cytoplasm admixed with islands of basaloid cells and areas of dystrophic microcalcifications (Figures 28, 29 and 30). A diagnosis of completely excised metatypical carcinoma was made.

Figure 28: Carcinoma islands with squamoid aspect, formed of polygonal, pleomorphic cells admixed with basaloid cells, infiltrating the conjunctive tissue, HE, 20x

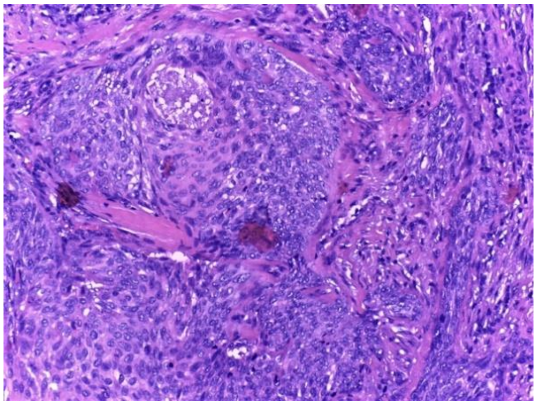

Figure 29: Islands of basal cell carcinoma with palisades and calcification, HE 10x

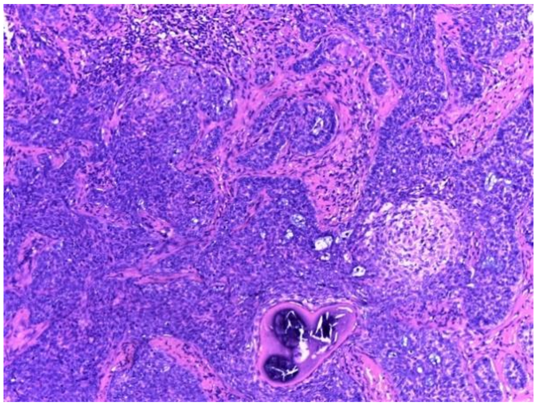

Figure 30: Association between component of squamous (cells with eosinophil cytoplasm, vesiculous nuclei) and basaloid cells (cells with basophile cytoplasm and tachychromatic nucleus) with calcification and incipient keratinizing, HE 10x

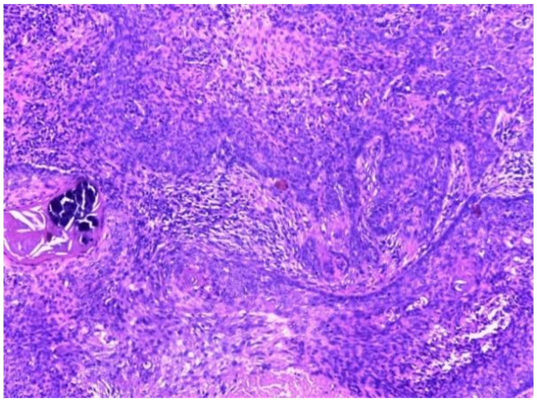

DISCUSSION

Among the skin neoplasms, two of the best known tumors are squamous cell carcinomas and basal cell carcinomas. Although the majority remain locally invasive, there is a risk of local-regional and remote dissemination. Considering the predisposition for basal cell carcinoma to appear on the head and neck in 70-80% of cases, and also the size of tumor, the metastasis rate is appreciated at around 0.0028-0.55% [8,9,10]. Regarding squamous cell carcinoma, it was demonstrated that the tumor size, depth and perineural invasion increased the risk of metastasis. The tumors measuring more than 2 cm in thickness that infiltrated into the deep skin structures or the bone, counted for 75% of the metastases [11]. The current guides target a much more detailed analysis considering the perineural invasion, thickness of tumor and dimensions of free margins of tumors for squamous cell carcinomas. It can be extrapolated that these prognostic factors can be applied to basosquamous carcinomas, especially for those with an important squamous component [12]. In our study, only the patient with perineural invasion was reported to have an increased risk of relapse.

Although few cases of basosquamous carcinoma are reported in literature, it is important to notice that all of the 5 presented cases were identified only in a 2 months' period. Hence, it is expecting to increase the incidence for this subtype of skin cancer.

To some researchers, the basosquamous carcinomas are presented with metatypical basal cells and histopathological characteristics of both basal cell carcinoma and of squamous cell carcinoma, with or without transition area between them. This neoplasm represents a controversial pathology since its first description in 1910, when McCormac reported a range of erosive ulcers classifying them in 3 types of tumors: pure, mixed (side by side basal and squamous cells) and intermediary subtypes. Subsequently, in 1912 Korbl presented a form of transitional skin cancer with a structure of basal typical cell carcinoma but with bigger, pallor cells, rich in cytoplasm and containing intercellular bridges.

The term of metatypical epithelioma was introduced in 1922 by Darier, presenting it as a typical basal cell carcinoma with conglomerates of squamous cells.

In 1928, the notion of epithelioma with basosquamous cells appears, pursuant to a study of Montgomery that reported a transitional area between squamous cell carcinoma and basal cell carcinoma. In 1951, Thackray accepted basosquamous carcinoma as an entity, although he did not define it. Multiple contradictions related to such neoplasms existed along the years. Some researchers considered them as a variant of basal cell carcinomas with keratinizing areas but without prognostic signification [13].

The terminology of such neoplasm still raises controversies since the literature does not clearly defines it. Currently, it's being recognized as being an aggressive form of basal cell carcinoma, with a risk of relapse ranging between 10-48% and a risk of metastasis between 5-7.4% [14].

In opposition, Martin et al. didn`t take in consideration the degree of differentiation and size of initial tumor as factors predisposing to relapse. The positive indicators considered were positive excision margins, lymphatic and perineural [15].

Leibovitch proved in a 178 patients study, that 95% of basosquamous carcinoma were located on head and neck regions having an increased predisposition for the nose (33,1%), auricular region (18,5%) and eye area [16].

It is interesting to notice that similar to the literature's data, all the tumors described in this paper were located on head and neck regions, on sun exposed areas, and affected patients with an average age of 76.6 years. Macroscopically, all tumors had an erosive nature with an aggressive growth, except for the case no. 4 which had an evolution of approximately 10 years. In case no 4, multiple ganglia images (one mediastinal, axillar, submandibular and on bilateral carotid space) were found. The literature presents the risk of metastasis in basosquamous carcinoma higher than that of basal or squamous cell carcinoma, with pulmonary prevalence [17]. Thus, correlating with the literature data, the presence of the adenopathies and the dimension of the tumor are associated with bad diagnostic and risk of relapse. Also, slow evolution of case no 4, during ten years, shows the necessity of studying the squamous component prevalence in the evolution of these tumors, as much as the predisposing factors or precursor lesions.

It is important to mention that some studies show an aggressiveness of basosquamous carcinoma higher even than that of squamous carcinoma [18].

Macroscopically, we notice that such tumors have ulcerative, erosive nature, a feature proven also by Cigna et al based on a retrospective study including 312 patients with metatypical carcinomas [19].

Another aspect that needs to be taken into account is the tumor's location, especially on head, which represents a challenge for both the surgeon and the patient. Many times, wide, meticulous excisions are needed, and several vascular-muscular-nervous important elements are encountered. Therefore, the complex reconstructions could be mutilating to the patient.

Paraclinical, the only common abnormal marker found at the patients included in the study was increased rate of blood sedimentation, which is a nonspecific marker of inflammation. Even if they have macroscopically similar tumor features like erosive and ulcerated characteristics, the evolution was impredictible, from a few months to ten years. This it increases even more the necessity of studying the role of the squamous component percentage in the basosquamous carcinoma evolution, together with the skin response at sun exposure and inflammation.

Although the treatment of basosquamous carcinoma is not optimized, we need a more carefully approach both surgically and imagistically to evaluate the existence of disseminations, as well as oncologically with a very strict follow up. In our study, one of 5 patients received radiotherapy (case no 4).

One year postoperatively none of the patients presented local relapse, confirming that the tumor free-margins are the key for a good management of this pathology.

For a relevant treatment, it is important that the correct diagnostic is made based on histopathological examination. In cases of basosquamous carcinoma, the immunohistochemical determination with EP-CAM and CD10 markers may be useful, basal cell carcinomas being positive and squamous cell carcinomas negative [20]. CXCR4, MMP-13 and b-catenin may also be considered as prognostic markers [21].

The particularities identified based on immunohistochemical reactions rise even more attention on the necessity of treating basosquamous cell carcinoma as a unique entity with an unpredictable evolution and an aggressive pathway. We noted that basosquamous carcinomas may also have overlapping immunohistochemical features found in both basal cell and squamous cell carcinomas.

CONCLUSION

Given the increasing incidence of basosquamous carcinomas and unpredictable evolution, sometimes even more aggressive than squamous cell carcinoma, there is a clear need for an optimized therapeutic protocol and a correct diagnosis based on histopathological and immunohistochemical examinations [22,23]. Treating as a different entity than typical basal and squamous cell carcinomas, understandying the pathology and approaching the role of squamous component in its evolution, should be considered. Resection with tumor- free margins and correct histopathological examination are the key features in the approach of basosquamous carcinoma, backed-up by oncological approach and a rigorous follow up. The development of non-invasive tests concerning modifications, surprising the carcinogenesis in situ, and the education of people regarding sun exposure and skin cancer, are also two important steps to decrease the incidence of skin carcinomas.

CLINICAL PRACTICE

Bilateral pneumatization of middle and superior nasal turbinates

Mugurel C. Rusu[1], C.J. Sava[2], Mihai D. Stoenescu[3]

Abstract: *The pneumatization of all nasal turbinates is an extremely rare finding. Several previous reports have presented the bilateral superior, middle, and inferior conchæbullosæ. We report the bilateral pneumatization of middle and superior nasal turbinates. The variant was documented in cone beam computed tomography (CBCT) in all three dimensions. The inferior concha bullosa was a bilaterally moderate subtype of lamellar pneumatization that presented as a conchal recess of the maxillary sinus. The concha bullosa media was bilaterally of the extensive or true type and associated unilaterally with an uncinate bulla. The concha bullosa superior was asymmetrical bilaterally, narrower on the right side, and larger on the left where it was also septated and tri-cameral. The supreme conchæ were rudimentary, as were their pneumatizations. For an accurate anatomic diagnosis of conchæbullosæ in computed tomography, sagittal, coronal, and axial cuts, as well as three-dimensional reconstructions, should be used to ensure adequate planning of functional endoscopic sinus surgery.*

Keywords: *agger nasi; ethmoid bone; nasal fossa; nasal concha; nasal turbinate; anatomic variation*

INTRODUCTION

The lateral nasal wall attaches the nasal turbinates or conchæ. The inferior one is an independent bone. The middle, the superior, and the inconstant Santorini's supreme turbinates are the ethmoidal turbinates that are attached on the nasal side of the ethmoidal labyrinth [1].

A concha bullosa defines the pneumatization of a nasal turbinate. Although the term is commonly used to indicate the pneumatization of the middle turbinate, other nasal turbinates (inferior, superior, and supreme) have also been found to be pneumatized [2-15].

Sagit et al (2008) reported the first case of the pneumatization of six turbinates [16]. Fidan (2012) also assumed that the "pneumatization of all turbinates in a person has not been published yet" and suggested the term "panconcha bullosa" for such pneumatization of all six turbinates [17]. Ozturan et al (2013) failed to document these two previous reports and presented a case with "bilateral triple turbinate pneumatisations," noting, "Despite an extensive search of the medical literature, we could locate only one description of extensive turbinate pneumatisation involving anywhere near as many conchae as in our patient" [18].

Moreover, Bergman's Comprehensive Encyclopedia of Human Anatomic Variation [19] indicated only that the "pneumatization of several turbinates in the same patient has been reported," citing the reports of Sagit et al (2008), Ozturan et al (2013), and a third paper in which Pittore et al (2011) reported only a case of concha bullosa inferior [10], and not a panconcha bullosa. The reports of Fidan (2012) and Toplu et al (2013) were omitted [15, 19].

We therefore report the fifth known case in the literature of the pneumatization of all nasal turbinates. To our knowledge, it is the first such case being documented in cone beam computed tomography (CBCT) and not on coronal CTs, as well as the first case in which findings were equally documented with bi-dimensional multiplanar reconstructions (MPRs) and three-dimensional volume renderizations (3DVRs). Nevertheless, we hereby report the pneumatization of eight, and not six, turbinates, as well as Santorini's first supreme turbinate was also found to be bullous.

ANATOMIC VARIATION

A retrospective CBCT study of the archived files of a 52 years old female patient was performed.

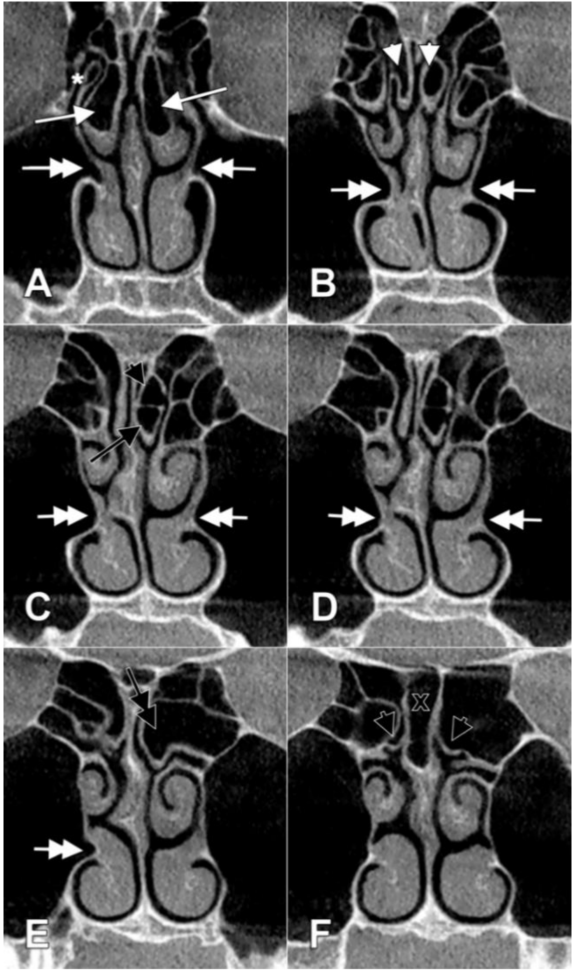
The subject had been scanned using a CBCT machine – iCat (Imaging Sciences International), the DICOM file being further documented with the Planmeca Romexis Viewer 3.5.0.R software, according to a previously detailed protocol of study [20-23]. We evaluated the nasal turbinates in all the three anatomical planes, as well as the three-dimensional volume renderizations. Relevant anatomical features were exported as image files. The patient has given written informed consent for all medical data to be used for research, provided they are anonymized.

In the case hereby reported, a Type 5 Mladina nasal septal deformation was found, with a horizontal septal spur sticking laterally and deeply in the right nasal fossa between the middle and inferior turbinates (Figure 1). The postero-superior part of the nasal septum accommodated an anterior (septal) recess of the right sphenoidal sinus. However, the septum did not appear deviated.

The inferior turbinates were bilaterally pneumatized by conchal recesses of the maxillary sinuses (Figures 1A–E, 2, 3F, 4, 6). The conchal pneumatization penetrated the horizontal segment of the lamellar part of each turbinate (Figure 6), with a 6.10 mm depth on the right side, and 3.02 mm depth on the left side (on coronal slices). These inferior conchæ bullosæ were located between the ethmoidal and maxillary processes of the inferior turbinate (Figure 6).

We also found bilateral pneumatizations of the middle turbinates (Figures 1A, 3, 4). These were both extensively pneumatized (true or extensive concha bullosa media) and were draining in the middle meatus on that side. An uncinate bulla was found unilaterally on the outer side of the right concha bullosa media (Figure 1A). It was pneumatized from an anterior adjacent lacrimal cell located, in turn, posterior to the agger nasi cell.

Figure 1: Anterior to posterior series (A–F) of coronal MPRs identifying the eight turbinates' pneumatizations. The beaked-shape pneumatization of each inferior turbinate is identified (A–E, white double-headed arrows). The bilateral concha bullosa of the middle turbinates (A, white arrows) is of extensive type, lamellar and bulbous. A right uncinate bulla is found (A, *). The superior turbinates are bilaterally pneumatized (B, white arrowheads). A horizontal septum divides the anterior part of the left superior concha bullosa in two chambers, superior (C, black arrowhead) and inferior (C, black arrow). Both drain into the upper nasal meatus (C, D). A third posterior chamber of the left superior concha bullosa (E, black double-headed arrow) appears as a medially evaginated posterior ethmoid air cell. On both sides of an anterior (septal) recess („X") of the right sphenoidal sinus the rudimentary supreme turbinates also appear pneumatized (F, black arrowheads).



We also observed a bilateral concha bullosa superior (Figures 1B–E, 3-6). The conchal air space was narrow in the right side (1.75/4.01 mm on coronal slices). The left concha bullosa superior was larger (4.81/11.35 mm on coronal slices) and septated by an overturned "Y"-shaped septum (Figures 3A, 5).

Thus, it consisted of three chambers: antero-superior, antero-inferior, and posterior. The anterior chambers were draining in the left superior nasal meatus (Figures 1C, D).

Figure 2: Axial MPR demonstrating the bilateral inferior concha bullosa (double-headed arrows).

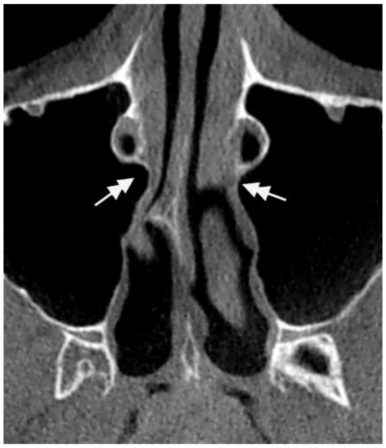


Figure 3: Lateral to medial series (A–F) of sagittal MPRs of the left lateral nasal wall. An agger nasi cell (A–F, *) is found anterior and superior to the anterior end of the middle nasal turbinate. Posterior to it lies the middle concha bullosa (A-–, white arrow). The inferior concha bullosa is indicated (F, white double-headed arrow). The superior concha bullosa is double-septated and consists of three chambers (A, B, white arrowheads): two anterior and one posterior. The posterior one is a conchal recess of a posterior ethmoid air cell (B–F, „X”), as is the supreme concha bullosa (D, black arrowhead). The superior (black arrow) and supreme (black double-headed arrow) turbinates are indicated (C–E).

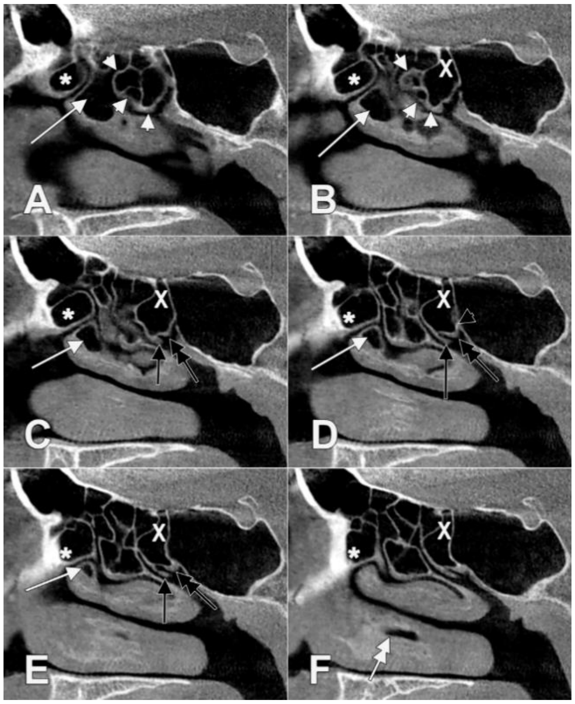

The posterior chamber appeared as the extension (conchal recess) of a posterior ethmoid air cell which, in turn, was also extending to form the left concha bullosa suprema (Figure 3).

As the concha bullosa suprema was also found on the right side (Figures 1, 3–5), we recorded this variation as bilateral. The rudimentary supreme conchæ bullosæ appeared as small diverticula of the respective posterior ethmoid air cells.

Figure 4: Sagittal MPR of the right lateral nasal wall crossing thorough all four conchal pneumatizations: inferior (double-headed arrow), middle (arrow), superior (white arrowhead), and supreme (black arrowhead).

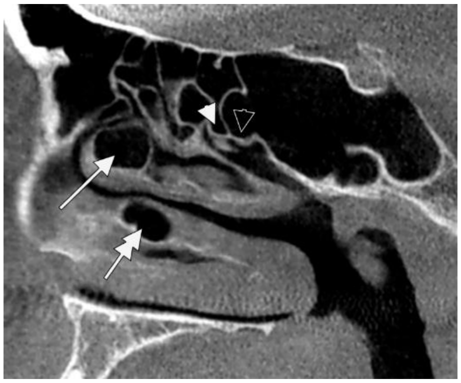

Figure 5: Three-dimensional sagittal volume renderization of the left lateral nasal wall. The superior concha bullosa is separated by septa in three chambers (diverging thin arrows). A posterior ethmoid air cell ("X") pneumatize the posterior chamber of the superior turbinate (white arrowhead) and the supreme turbinate (black arrowhead). The thick arrow indicates the middle concha bullosa and the double-headed arrow—the agger nasi cell. FS: frontal sinus; SS: sphenoidal sinus; IT: inferior turbinate; NS: nasal septum (partly).

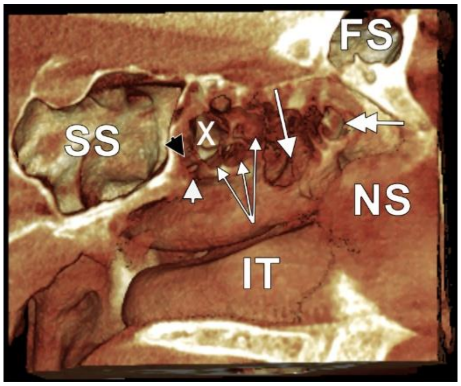

Agger nasi cells were found bilaterally. The right one was draining in the frontal recess and the left one in the ethmoidal infundibulum (Figure 7).

DISCUSSION

As was already discussed in the Introduction, reports of panconcha bullosa, such as this one, are rare. The nasal septum typically deviates away from an asymmetrically enlarged dominant concha bullosa [7].

Nasal septum deformities were classified by Mladina, the left-sided deformities being more prevalent than the right-sided ones [24]. According to these authors, type 5 indicates "an almost horizontal septal spur that sticks laterally and deeply into the nasal cavity," the opposite side of the septum being flat [24].

This corresponds to the septal morphology we found in the present case. The absence of an important septal deviation indicates that we encountered a case of bilateral pneumatizations balanced in size.

Figure 6: Three-dimensional coronal volume renderization of inferior turbinates (ITs). On each side, conchal recesses of the maxillary sinuses (MS) penetrate the turbinate roots (double-headed arrows) to form communicating lamellar inferior conchæ bullosæ. These pneumatizations are located on each side between the ethmoidal process of the ITs (1), which further articulates with the uncinate process (2), and the maxillary process of the ITs (3).

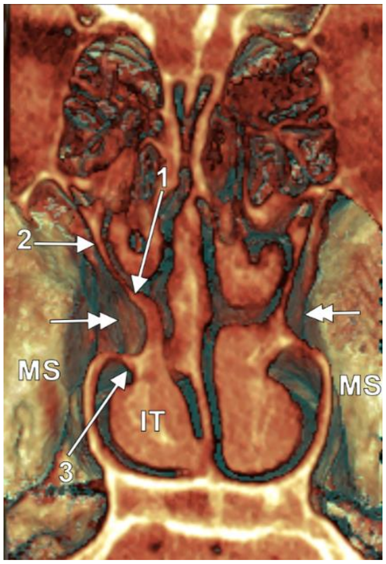

Figure 7: Sagittal MPRs demonstrate bilateral agger nasi cells (*). The right one communicates with the frontal recess (arrow), and the left one drains in the ethmoidal infundibulum (arrowhead).

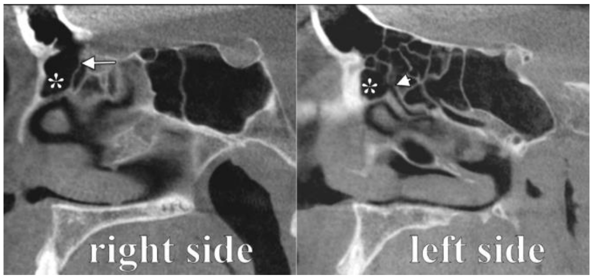

Figure 8: Reprinted from Hindawi – Turhan San, Selma San, Emre Gürkan, and Barış Erdoğan, "Bilateral Triple Concha Bullosa: A Very Rare Anatomical Variation of Intranasal Turbinates," Case Reports in Otolaryngology, vol. 2014, Article ID 851508, 2 pages, 2014. doi:10.1155/2014/851508, which is licensed under CC BY. We indicate (inset, digitally magnified) that the so-diagnosed left inferior conchal pneumatization is merely a strongly curved inferior turbinate, due to a septal spur that pushes the left inferior turbinate.

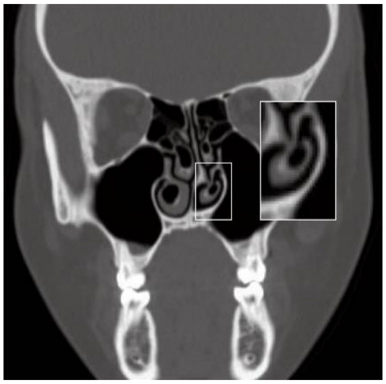

According to Kiroglu et al (2007), the pneumatization of the upper and middle nasal conchæ is commonly encountered, but a concha bullosa inferior is very rare [25]. Koo et al (2017) documented 1188 sides and found a unilateral concha bullosa media in 17.3%, a bilateral concha bullosa media in 36.4%, a unilateral concha bullosa superior in 11.3%, a bilateral concha bullosa superior in 27.4%, and concha bullosa inferior in only 1.0% [13]. A supreme concha bullosa was reported, to our knowledge, only once, by Măru et al (2015) [2].

The first report of an inferior concha bullosa as an anatomic possibility was that of Zinreich et al (1988), while the first paediatric case with a concha bullosa inferior was assumed by Kiroglu et al (2007).

Bolger et al (1991) evaluated in 202 patients the common anatomical variants of the middle nasal turbinate, such as its pneumatization and the paradoxical curvature [26]. In 53% of patients, the authors detected concha bullosa media [26]. They further classified the respective pneumatizations according to their location, within the lamellar part of the middle turbinate, or in its bulbous part, or in both these. It resulted in a classification of concha bullosa media, lamellar, bulbous, and extensive or true, respectively [26].

Further, Yang et al (2008) extended the classification of Bolger et al (1991) to the inferior turbinate [27]. Yang et al (2008) evaluated 59,238 sinonasal CTs and contributed 16 patients with concha bullosa inferior (pneumatized inferior turbinate) to the 28 cases they had already documented as reported at that time [5, 28-41]. They found that in relation with the maxillary sinus, a concha bullosa inferior can be either communicating or non-communicating [27]. This equally feeds the hypothesis of misinvaginated epithelium within the double chondral lamella of the developing inferior turbinate (the non-communicating type) and the hypothesis of maxillary sinus extension within the inferior turbinate (the communicating type) [27]. The communicating type of a concha bullosa inferior was found in 8/18 pneumatized inferior turbinates by Yang et al (2008), thus in 44% of the series. Yang further subdivided the communicating type of a concha bullosa inferior into three subtypes, according to the degree of communicative pneumatization (27). These are (a) a subtle type with a beaked shape of pneumatization, (b) a moderate type in which the pneumatization fills the superior part of the vertical plate of the inferior turbinate, and (c) a marked type, in which the pneumatization completely fills the vertical plate of the turbinate [27]. It is interesting to note in this context a study by Măru et al (2013) in which the authors investigated 100 cases documented by CBCT and found unilateral extensions of the maxillary sinus within the inferior turbinates in 6% and bilateral extensions in 16% , which they termed conchal recesses of the maxillary sinus. Although these last authors did not indicate these recesses as pneumatized turbinates, it is bona fide the same morphology previously described by Yang et al (2008) as pneumatized inferior turbinates. According to the Yang classification, in the case we report here, the inferior conchæ bullosæ we found are of the communicating lamellar type, i.e., the moderate subtype. They can be equally classified as conchal recesses of the maxillary sinuses, however. Such communicating conchal pneumatizations were also indicated as common cavities of the maxillary bone and inferior turbinates [42], thus antro-, or sino-conchal cavities.

One should keep in mind that, according to Yang et al (2008), pneumatized inferior turbinates could be either communicating with the maxillary sinus, or non-communicating. Therefore, a concha bullosa inferior that drains in the inferior nasal meatus is a false one. We support this comment with the report of a "bilateral triple concha bullosa" of San et al (2014), who documented such a concha bullosa inferior only on coronal CT in a four-reference paper in which the study of Yang et al (2008) was not quoted. This is a false concha bullosa inferior that communicates with the inferior nasal meatus, and not with the maxillary sinus; narrowing of the turbinate concavity is rather due to a septal spur on that side (Figure 8). The left nasal spur (Figure 8) corresponds to the apex of maximum left septal deviation and is higher than the right concha bullosa inferior. Therefore, the concha bullosa inferior was not bilateral, as is supported by Tomblinson et al (2016), who demonstrated that the apex of maximum nasal septal contralateral deviation is positioned more superiorly when a unilateral concha bullosa is present and that the severity of septal deviation increases in direct proportion to the concha bullosa's width [7]. Therefore, studies of conchal pneumatization should be evaluated in three dimensions and carefully documented.

In this study, we documented a septated concha bullosa superior that was not, to our knowledge, previously reported. There were, however, a few reports of septated concha bullosa media. The first septated concha bullosa media was found unilaterally and reported by Yanagisawa et al (2008) in a patient elected for functional endoscopic sinus surgery [43]. The second such case was reported by Perić et al (2009), who found a unilateral tri-cameral concha bullosa media [44]. A tri-cameral concha bullosa media was also reported later, by San et al (2013), and was also unilateral [45]. Septation of the middle turbinate is not significantly related to sinonasal pathologies [46]. As supported by our results, the septation of turbinates is not a specific feature of the middle one. Further studies should carefully observe whether the observed conchæ bullosæ contain septa that determine multiple drainage pathways of such pneumatizations.

CONCLUSION

In conclusion, the pneumatization of all nasal turbinates appears as a rare anatomic variation that sums the individual possibilities of the pneumatization of nasal turbinates. Conchæbullosæ are better documented in CBCT and in all three dimensions and, in turn, are of better use for surgeons dealing with functional endoscopic sinus surgery.

Conflict of interests

The authors declare that they have no conflict of interest.

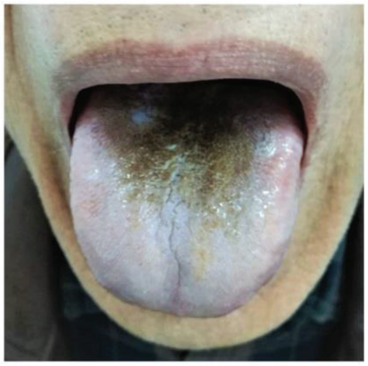
CLINICAL PRACTICE

Article received on May 15, 2018 and accepted for publishing on August 21, 2018.

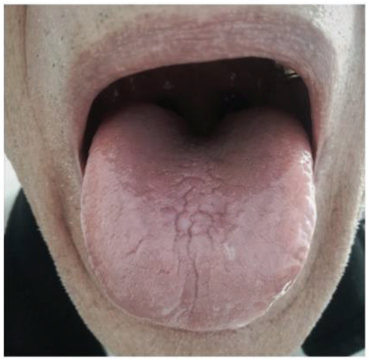
Black hairy tongue due to antibiotic intake

Catalina E. Lavric[1], Silviu V. Dumitrescu[2]

A 65-year-old man presented to our clinic for a sudden onset of black hairy tongue. The patient who has no significant medical history was explored 9 days before for non-specific gastrointestinal symptoms which had progressively accentuated in the past two months. Physical examination showed epigastric tenderness and bloating. Blood tests were within normal ranges but stool antigen test revealed Helicobacter pylori infection. Triple therapy was initiated with 1 gram amoxicillin, 500 mg clarithromycin and 30 mg lansoprazole, all recomanded twice daily for 14 days. In the 9th day he presented with a black hairy tongue which appeared "overnight".



Black hairy tongue represents a defective desquamation of the filiform papillae on the dorsal surface of the tongue, usually due to a lack of mechanical stimulation and debridement [1]. A range of medications [2] have been linked to hairy tongue including amoxicillin, penicillin, bismuth, linezolid. This condition is reported more often in males and the main problem is its unsighty appearance [3].



Sometimes patients may complain of a burning sensation on the tongue and halitosis. Black hairy tongue doesn't typically require medical treatment [4].

In this case the patient stopped the antibiotic intake on his own initiative and was encouraged to have a good oral hygene. He continued taking 30 mg of lansoprazole for three more weeks. One month later the tongue recovers its normal characteristics. Reevaluation of the stool test showed the efficiency of the short course of treatment, Helicobacter pylori being eradicated.

VARIA

Bladder injury – A team challenge

Monica Cirstoiu[1,2], Oana Bodean[1], Octavian Munteanu[1,3], Darius Brinzan[4], Bogdan Cretu[5], George Pariza[6], Popescu Dan[5], Catalin Cirstoiu[5,7]

Abstract: *Bladder trauma is caused by a direct blow to the distended bladder, severe injury fracturing the pelvis, iatrogenic, or penetrating wounds. Early detection and diagnosis are key to successful management of cases, but omission or late reveal of bladder damage increase mortality and create long-term problems. A bladder injury may not always present with immediate obvious signs and symptoms, especially in a multi-trauma patient, who is also more difficult to investigate. Moreover, during the COVID-19 pandemic, delayed patients' access to tertiary, multidisciplinary hospitals, increases the risk for delayed diagnosis and also increases the need for more specialists from different surgical and non-surgical areas to raise their awareness of less common manifestations of bladder trauma. We present a review of literature and cases of less common bladder damage from the perspective of a multi-disciplinary team in the University Emergency Hospital in Bucharest.*

Keywords: *bladder injury, pelvic fracture, urinary fistula*

BACKGROUND

Bladder injuries

Based on etiology, bladder rupture and injury can be blunt, penetrating, iatrogenic, or spontaneous. Anatomically, bladder injury can be extraperitoneal (40-60%), intraperitoneal (15-30%) or mixed (10-25%) [1].

Most of these injuries are caused by road traffic accidents, work-related accidents, falls, crashes, violent crimes, military conflicts, and iatrogenic maneuvers, such as obstetric, gynecologic, and urologic procedures [1, 2]. Common signs and symptoms of blunt bladder trauma are gross hematuria, suprapubic pain, abdominal bruising, extravasation of urine into the perineum and genital organs and thighs [1]. Delayed diagnosis may lead to peritonitis, fistula, and septicemia [1, 2]. In patients with other associated pathology or other associated trauma, undetected bladder injury can even be fatal [1].

Bladder fistula

A less common complication of delayed bladder injury

diagnosis is bladder fistula [1, 3]. Fistulas are abnormal communications within the genitourinary system or may involve other structures as the gastrointestinal tract, skin, vascular and lymphatic systems [1-3]. Bladder fistulas may involve the urethra, skin, gastrointestinal organs, female reproductive tract, and even pelvic joints [1, 2].

MATERIALS AND METHODS

Because bladder trauma and genitourinary fistulas are so diverse in their anatomy and clinical appearance, we present a review of literature about the less common occurrence of bladder trauma and our experience with this pathology.

Patients' data and imaging were collected from the University Emergency Hospital in Bucharest database.

RESULTS

Tertiary unit hospitals usually confront with multiple trauma patients who need a complex evaluation. Some of these patients come from isolated areas or after being initially partially evaluated in other healthcare facilities.

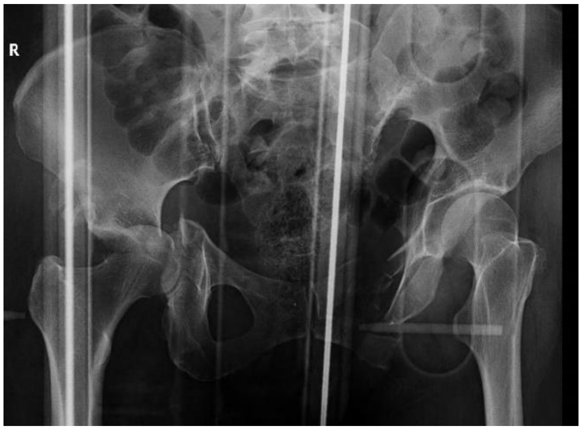
As described in the literature, most patients with bladder injuries present after obstetrics and gynecology procedures, intra-abdominal injuries (44-68.5%), or pelvic fractures [1-3]. The principal sign of bladder injury is visible haematuria, suprapubic pain, and urinary leakage, but according to the type of injury and the associated complications, bladder trauma diagnosis can be a real challenge for the specialists confronting with it. Usually, urologists and general surgeons are those who operatively manage the cases, but the nature and timing of intervention depend on additional complications and may require a differential diagnosis.

A complication of bladder rupture is a fistula, but rare types of fistulas, such as vesical-cutaneous fistulas associated with pelvic trauma have been sporadically described and no guidelines exist for their management. A particular type of posttraumatic bladder fistula with no immediate clinical manifestations is a vesical-vulvar fistula. As illustrated in the case below, these fistulas can often be mistaken for labial tumors or abscesses.

Posttraumatic bladder injury with vesical-labial fistula

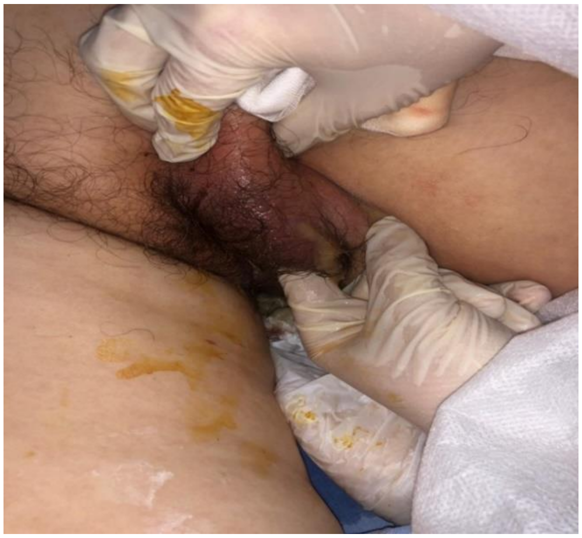
A gynecological and urological consultation was requested for a non-functioning urethral-vesical catheter of a 60 years-old female patient admitted in the Orthopedic Department that underwent surgery with external fixation 2 days prior for a complex pelvic fracture (transverse fracture of the right acetabulum, left obturator ring fracture, left sacral fracture, fifth lumbar transverse apophysis fracture with paralysis of the external left sciatic nerve) (Figure 1).

Figure 1: Preoperative x-ray scan showing a complex pelvic fracture type Tyle C2.



The patient presented with a left labial abscess with spontaneous exteriorization of content. Upon examination, the labial abscess raised suspicions due to the secretions exteriorized that were abundant and liquid, milky at first then clear (Figure 2).

Figure 2: Vesico-labial fistula in a patient with pelvic fracture and suspected bladder injury. The aspect could be easily misdiagnosed as a vulvar abscess.

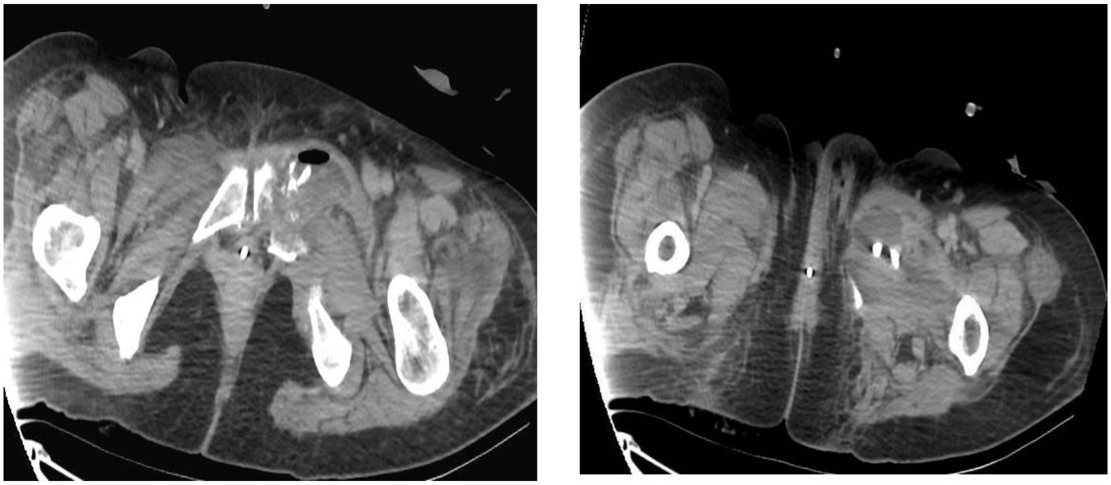


The suspicion of the vesical-cutaneous fistula was confirmed after administering methylene blue in the bladder via the functioning Foley catheter and observing the dye exteriorizing at the site of the labial orifice, therefore adding the diagnosis of extraperitoneal bladder injury complicated with a cutaneous fistula. The existing 14 CH Foley catheter was replaced with a 22 CH one and the external orifice of the fistula tract was drained with a draining tube.

The patient's recent history revealed the above-mentioned fractures with the left bladder wall tractioned laterally with no contrast extravasation 15 days before the consultation with surgical treatment delayed due to a positive RT-PCR COVID 19 test, the patient being transferred to a SARS-Cov 19 support Hospital. The onset or presence of hematuria in this time interval is not specified. The patient did benefit from bladder drainage, but with multiple clogging and rather unfunctional drainage before our consultation.

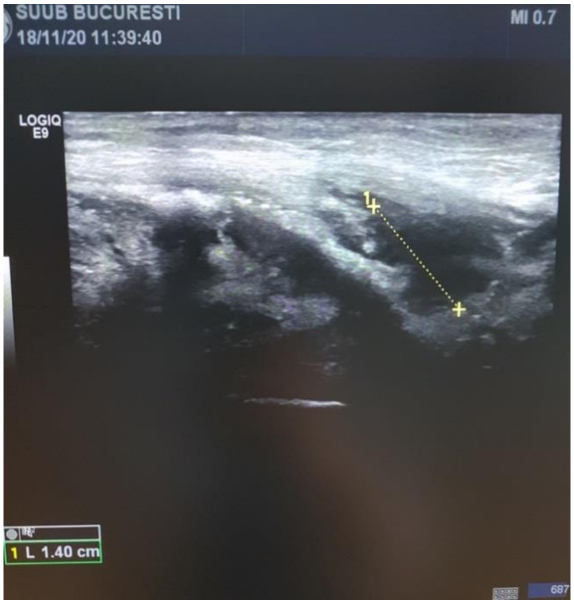
A second CT-scan was requested and confirmed the suspicion of vesical fistula (Figure 3) and revealed fluid accumulation (10/5.5/3cm) in the left external obturator space.

Figures 3: CT-scan showing complex pelvic fracture and the communication between the bladder and the left labia.



A second draining tube was inserted in this space with ultrasonic guidance to drain intramuscular collections (Figure 4).

Figure 4: Ultra-sonographic aspect of fluid and pus collection on the fistulous trajectory of the vesical-labial fistula.



Since the urological consultation and the diagnosis of the fistula took place 2 days after the patient underwent external fixation surgery, the possibility for concomitant primary bladder repair was excluded, leading to the decision for conservative management, with antibiotic treatment, monitored diuresis, and drainage. In case of a favorable outcome, the conservatively treated bladder injury will be followed by cystography to rule out extravasation. On the other hand, if the conservative treatment fails, the patient will undergo abdominal surgery for bladder repair.

The particularity of this case is that the bladder rupture presented with unspecific signs and symptoms, with a rather unusual fistula. The nature of the pelvic fracture, the malfunctioning catheter drainage, and the postoperative status of the patient leads to a more difficult and delayed diagnosis and management of the bladder injury.

DISCUSSION

Researchers found that 85% to 100% of bladder injuries are associated with concomitant pelvic fractures [1-3]. The bony spicules of a fractured pelvis and the shearing forces are the underlying mechanisms of extraperitoneal bladder rupture. Extraperitoneal injury is almost always associated with pelvic fractures [2]. The highest risk of bladder injury was found in disruptions of the pelvic circle with displacement > 1 cm, diastasis of the pubic symphysis > 1 cm, and pubic rami fractures [3, 4].

Intraperitoneal bladder rupture most commonly occurs on the dome of the bladder because it is the least protected area. Direct blow and deceleration forces are the underlying mechanisms. Urine leaking into the abdomen can be absorbed by the peritoneum, causing increased urea and creatinine, metabolic alterations, and low urine output. Infected urinomas can cause pelvic abscesses and peritonitis. Mixed intra- and extraperitoneal bladder rupture are less common, occurring in 8% of bladder injuries associated with pelvic fractures [5].

Diagnosis of bladder injuries can be challenging due to the often vague and non-specific presentation. Literature studies found that up to 23% of all bladder and urethral injuries associated with a pelvic fracture are missed at initial evaluation [6]. Moreover, other studies highlight the delay in diagnosis since the patients were from isolated areas, with poor access to a tertiary trauma center [7].

Iatrogenic bladder injuries are not uncommon. The bladder is the most frequently injured organ during obstetric and gynecologic interventions, such as hysterectomies and cesarean sections. Frankman et al. reported an incidence of 13.8 bladder injuries per 1000 procedures in 2010, but as the incidence of cesarean sections has increased worldwide, the incidence of urologic injuries is expected to rise as well [8].

Vesicovaginal fistula is the oldest described type of fistula. It may occur as a complication of childbirth, hysterectomy, irradiation, and trauma. Patients with neoplasms of the cervix and bladder, especially those who underwent irradiation, are more prone to develop vesicovaginal fistulas [1,4]. Vesicocutaneous fistulas occur after surgical procedures or trauma. Those occurring at suprapubic cystostomy sites after catheter removal usually close spontaneously.

A rare complication of pelvic trauma with bladder injury is a vesical-vulvar fistula, which can be misdiagnosed as a labial tumor or abscess. Also, a vesical-articular fistula can involve the hip joint, causing septic arthritis [9].

Imaging diagnostic methods of bladder trauma and fistula

According to literature studies, conventional intravenous abdominal/pelvic CT will miss 40% of bladder ruptures [1, 10]. Absolute indications for bladder imaging include visible haematuria and a pelvic fracture or non-visible haematuria combined with high-risk pelvic fracture (disruption of the pelvic circle with displacement > 1 cm or diastasis of the pubic symphysis > 1 cm) or posterior urethral injury [4]. Cystography is the preferred diagnostic modality for non-iatrogenic bladder injury and a suspected iatrogenic bladder trauma in the postoperative setting [11]. CT cystography has a higher sensitivity and specificity (99-100%). Both the American Urological Association (AUA) and the European Association of Urology (EAU) recommend either plain-film or CT retrograde cystography for detecting bladder injuries in all suspect patients. In critically ill patients, when cystography cannot be initially performed, a Focused assessment with sonography for trauma (FAST) exam can be used. Bedside ultrasonography with intravesical saline instillation may assist in the early diagnosis of bladder rupture, but it depends on the ultrasonographer's experience [12, 13]. Ultrasonography can also detect intra or extraperitoneal fluid. In the case of pelvic fracture, CT-cystography is superior in detecting bony fragments within the bladder [2, 13]. Cystoscopy is the preferred method for the detection of intraoperative bladder injuries as it directly visualizes the laceration and can localize the lesion concerning the position of the trigone and ureteral orifices [14]. Large perforations are suggested by the lack of bladder distention during cystoscopy.

Imaging diagnostic methods of bladder fistula also include fistulography, cystoscopy, and voiding cystourethrography.

In large vesicovaginal fistulas, urine leaking into the vagina can be easily seen, or methylene blue dye can be used to mark the fistulous path [15].

Management options from international guidelines

The EAU states that the majority of uncomplicated extraperitoneal bladder injuries can be managed with catheter drainage alone and will heal in about 14 days. Conservative management, which comprises of clinical observation, continuous bladder drainage, and antibiotic prophylaxis is the standard recommended treatment in all uncomplicated extraperitoneal injury due to blunt or iatrogenic trauma [16, 17]. In any patient with penetrating or intraperitoneal injury, emergency exploration and repair are recommended even in the absence of pelvic fracture. Bladder neck involvement, bone fragments in the bladder wall, concomitant rectal, or vaginal injury, or entrapment of the bladder wall necessitate surgical intervention [5].

Orthopedic management of pelvic fractures includes internal fixation or temporary external fixation. Given the increased infection risk associated with prosthetic material used in orthopedic surgery, urologists are advised to consider primary repair of uncomplicated bladder injuries to reduce the risk of colonized urine infecting osteo-synthetic material (EAU guideline, Grade B recommendation). Recent studies comparing conservative management to concomitant bladder repair in the setting of internal fixation found an increased risk of infection in patients that did not benefit from concomitant bladder repair [18, 19]. Therefore, bladder repair is recommended at the same time with the internal fixation and exploration for other injuries to decrease the risk for complications and to reduce recovery time [20-22].

Bladder closure is performed with absorbable sutures. There is no evidence that a two-layer is superior to watertight single-layer closure [2, 23].

Follow-up of patients with bladder injury must always include bladder drainage to prevent elevated intravesical pressure and to allow the bladder to heal. Conservatively treated bladder injuries must be followed up by cystography to rule out extravasation and ensure proper bladder healing [4]. The first cystography is planned approximately ten days after injury. In case of ongoing leakage, cystoscopy should be performed to rule out bony fragments in the bladder, and a second cystography is warranted one week later [24, 25]. Cystography is always advised in cases with complex injury (trigone involvement, ureteric reimplantation) or with risk factors of impaired wound healing [13, 15]. In healthy patients with a surgical repair of a simple bladder injury, the catheter can be removed after 10 days without a cystography. Some authors recommend drainage catheter removal after 5 days in conservatively treated internal iatrogenic extraperitoneal bladder perforations and after 7 days for extraperitoneal perforations [11, 22].

Management options for vesico-vulvar and vesicovaginal fistula

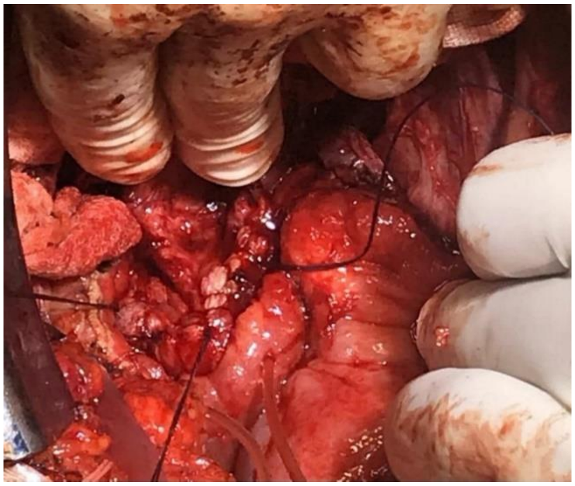
The treatment of choice for vesicovaginal fistulas is surgical, although spontaneous closure of small fistulas with simultaneous permanent catheterization for 19-54 days is mentioned in the literature. Approximately 10% of vesicovaginal fistulas from hysterectomy resolve conservatively if the fistula is small (<1cm, <1.5cm), is recent and the Foley catheter is inserted as soon as possible [26-29].

Thus, if a fistula does not close spontaneously in 4 weeks, surgery is needed. Hillary et al. described high percentages of success for the vaginal approach of fistula repair (90.8%) as compared to the abdominal approach (83.9%) [30]. Studies about fistula approach and follow-up are generally scarce and report small numbers of patients. Kapoor et al., in a study on 52 cases, for which he used vaginal and abdominal approach, found that vaginal approach is superior in uncomplicated cases, with small fistulas, but an intraabdominal repair is mandatory for extragenital fistula, for highly situated fistula, when reimplantation of ureters is needed, or when the vaginal approach is impossible [31].

The best timing to proceed to surgical repair is between 3 to 6 months from the appearance of the fistula. Ideally, the best time would be in the first 2 weeks, before bladder inflammation and fibrosis appear, but unfortunately, it takes more than 2 weeks for the fistulas to be detected.

The surgical approach may be transvaginal, transabdominal, or transvesical. Bilateral ureteral catheterization before intervention is recommended, as illustrated in Figure 5. A Foley catheter will also be kept in place for 14 days and removed after a prior retrograde cystography [32].

Figure 5: Intraoperative image of a transabdominal repair of a vesical-vaginal fistula in a post-hysterectomy patient. Ureteral catheterization was also performed and the bladder was sutured.



Vesico-labial fistulas are rare and have been scarcely described by literature. Their initial appearance which can lead to the misdiagnosis of vulvar abscesses and the need to primarily address the associated lesions makes this type of vesical-cutaneous fistula to have a later diagnosis and lead to a later approach by transabdominal repair.

CONCLUSIONS

Bladder rupture must be suspected in multi-traumatized patients with complex pelvic fractures, even in the absence of immediate onset of common symptoms like gross hematuria.

Because 40% of bladder injuries are missed at first emergency evaluation, repeating CT scans and using additional imaging techniques can reveal the bladder injury and other posttraumatic lesions.

Vesico-labial fistula is a rare complication of a delayed diagnosis of posttraumatic bladder rupture that can be easily misdiagnosed as a vulvar tumor or labial abscess, requiring a different approach to fistula repair.

Conservative management is the treatment of choice in a patient who already underwent surgical external fixation for pelvic fracture as long as the bladder injury is not complicated by infection and the bladder fistula is small. Bladder drainage with a large Foley catheter is mandatory, with permanent surveillance of catheter functionality and antibiotic prophylaxis. Concomitant bladder repair with internal pelvic fixation or other abdominal wound exploration is recommended to decrease complications and healing time.

The correct diagnosis and management of such cases always require a multidisciplinary team, including urologists, general surgeons, orthopedists, Ob&Gyn specialists, and radiologists.

Medical teams must raise their awareness of potential insidious complications of bladder injuries as some diagnosis can be delayed or incomplete due to the challenges that come with the COVID19 pandemic.

Blending between occultism and scientism in Vasile Voiculescu's short stories

Mirela Radu[1]

Abstract: *Vasile Voiculescu (1884-1963), besides being a well-known writer, was also a prominent, much respected physician who practiced between the two world wars. He attended the courses of the Faculty of Letters and Philosophy in Bucharest for a year (1902-1903), but gave up on them in order to attend the Faculty of Medicine. The literary debut took place in 1912 in the journal Convorbiri literare. He published the first volume of lyrical poems in 1916 and in 1918 he was granted the Academy Award for lyrical volume From the Aurochs Country and other poems. In 1935 he became a member of the Academy of Sciences of Romania and in 1941 he received the National Poetry Prize. The following volumes of poems are: Ripeness (1921), Poems with Angels (1927), Destiny (1933), Ascent (1937), Gleams (1939). His work also includes a short story: The Demiurge (1943). Shakespeare's last imaginative sonnets in Vasile Voiculescu's translation (1964), and the novel Zahei-The blind (1966), Sentimental Gymnastics (1972) are published posthumously. The present article is aimed at revealing the world of Voiculescu's short stories.*

Keywords: *medical studies, abyssal psychology, scientism, mystery, obscurity*

Although the most analyzed part of Voiculescu's work seems to be his poetry, he proved his worth in the same manner in storytelling. His creative enthusiasm needed several means of expression as Voiculescu the poet was sometimes haunted by a "spirit of storytelling manifestted as a spontaneous eruption." [1]

His inspiration manifested itself as prose also because creative adaptability seems to grow with age: "As the man seemed to «bend under the weight of the years», the creator received new powers, as a sum of his life's and artistic experience by a high level of expression, in a veritable eruption if poetry, in verses and prose." [2] The surprise comes from the chameleonic nature of the author who took on prose with different motives than those in his poetry, coming out as a writer who was: "(…) a perfect master of his own means, not related in any way with the poet." [3] Voiculescu's stories are that much more appealing as they give the sensation of combining some fantasies from the folkloric supernatural, amusing stories, hunting adventures but also "(…) oddities to be told at midnight, parapsychological medical cases etc., which the author attributes a narrative density, emphasizes their equivoque and gives them a superior meaning through the means of literature." [4]

What characterizes the doctrinal physicist's stories are miraculous happenings populated by divine characters

[1] Titu Maiorescu University, Faculty of Medicine, Bucharest

with an occult composition, “(...) in which «the efficiency of symbols» is not alien to the writer's anthropomorphic manner.” [5] Some of his stories seek to demystify believes: the conviction that the shadow building can lead to death (The shadow, 1935), even to the actualization of some pseudo-scientific procedures of rejuvenation fashionable at the time, among which the method of doctor Sergiu Voronoff for grafting of some glands called by him interstitial, a method that was widely debated in the periodicals of the time [6] (The Demiurge, 1943) [7]. The connection between certain life forms represents the main theme in the physician’s novellas. The influence of medical studies is present due to the fact that Voiculescu combines the folkloric preconceptions with scientific revelations and with: “the hypothesis and conclusions of modern experimental psychology (…). [8] The reason for his leaning towards folkloric heresies was the fact that, being in a permanent search for answers, the literate-physician did find them even in practiced medicine. Unlike other prose writers with folkloric roots, Voiculescu’s characters are fantastic with occult origins. Some critics noticed his short stories astonishing capability of entwining the new with the old, and of “discovering pathways of the archaic in the modern, some depths of existence itself, this causing Voiculescu to write some of his best prose.” [9]

Supernatural, mystery and obscurity were what fascinated him, ticking his interest even before his medical studies in :”(…) heresies, magical symbols, in one word the occult part of existence.” [10] Unavoidably, the permanent dispute in his soul between objectivity and belief can be seen in his work. A proof in this this sense is represented but the fact that in his short stories, the author uses characters that, if not belonging to the medical world, at least belong to the scientific one, meant to shed an accessible perspective of fantastic events to the reader. These characters can be considered an alter-ego of the author, his nature of undressing every fantastic element by finding a clear explanation, or are either introduced in order for the reader to decipher the message. In a world in which the occult loses ground to the prosaic, these characters anchored in the real world have the task of opening doors through which a new reality can be either seen or understood.

The separation of social and personal life is impossible. This can be seen in Voiculescu’s work. The contaminations from one to another: living scientifically but sensing aesthetically can be found in written pieces: “(…) the diagnostician and the therapist can be found, in way or another in writing (…) but the physician-writer relationship can reside in other places too and can be the subject of a study on man, as a professional in medicine but also in prose, who borrows aspects of the life and work of the former.” [11] This combination can only occur by presenting bizarre medical cases, almost always pathological.

To prove this deduction, Florentin Popescu brings the example of the short story The cursed cow (written by the literate-physician in only one day, 27th February 1947) which portraits the morbid case of zoophilia between a spoon maker who satisfies his sexual urges with the cow, Dumana. The short story Dead season (2nd June 1948) from the volume Magical love appeals to psycho-analysis. This time, the character dominated by rationalism- physician Charles and his dog Azor are preyed upon by a mysterious force. Azor mates with a fox and the medic with a peasant. Everything comes back to normal when the mystical element, the fox, is slain. The explanation that the rational man-Charles-tries to attribute to the semi-hypnotic event is insolation and the effect that the moon had on him: “Meaning that his brain was struck by the too powerful light of the moon. Like others get insolation, there are some more sensible to the magnetic waves of the moon.” [12] Some exegetes saw this piece as a case of “ecological Freudiansim” [13], a way of setting loose the sexual restraints. The same as in other stories of Voiculescu, the deeds are described by a narrator which seeks to be objective, doctor X, “… medic and poet in his free time.” [14] This same narrator has he role of arguer, even if he doesn’t acknowledge his ability to psycho-analyze the events “I am not a psychologist and less a Freudian (…) I never sought an explanation for humanism that erupted in him covering the self-imposed artificially to himself.” [15] The writer does not judge, and nor does he incline the scale towards cabalistic or rationalism, he just offers facts left for the reader to judge and decipher. "His interest goes towards a magical underlay in the peasant's spirituality, which he does not judge or condemn." [16]

Dramaturgy represents another aspect under which the inner torments of the Voiculescu, the physician-literate, developed on paper. Among his plays are The wanderer, Sentimental Gymnastics and The Demiurge. In Sentimental Gymnastics, a commoner, Ion Ionescu, comes in touch with psychological elements from William James' doctrine when he receives training, from an ex-colleague – Puiu Moldovian, in repressing affective emotions. The purpose of this training is that of freeing the character from doubts and boosting his self-esteem. If professionally this turn of events is favorable to him, sentimentally it ends in a failure as he becomes too attractive to the women in his town who will fall prey to his charm.

The influence of Expressionism can be seen in the short story On the miracle doorstep (1934) also named dramatic poem in which the issues of religion and fantasy are exposed. Itic Holzfleisch carries the burden of introducing a new religion to mankind. Because of his lack of credibility he is arrested. In prison he hangs himself behind the door where passers could not see him. Because of his supposed disappearance Itic is thought to indeed possess supernatural powers and can become invisible. The miracle though is not fully completed, hence the key in the title – "on the doorstep" – meaning on the edge. Ovid. S. Crohmălniceanu identifies a Verkundigung Drama in this short story. By not respecting any canons, this short story presents itself as an "authentic modern «mystery»." [17] Religious in appearance, the short story could be labeled in the template set by Gândirea, but by shedding light on the main character's inner feelings, the critic perceives it as expressionistic. The same Ovid. S. Crohmălniceanu considers another two short stories belonging to the same literary current, The shadow and The bear's girl, both published in 1930 and then included in 1943 into The Earth's spirit.

The short story The Demiurge (1943) precedes the nightmare that Europe would live three years later: the second worldwide conflagration and the Nazis' experiments for perfecting the pure race. This time, the main character is yet again a medic: Muşatin. Descendant of an old family he seeks to refresh his family's genealogy by gene amelioration. In order to do this, he focuses on experiments, at first on animals, and later on human beings. Lucian, his son, does not agree with his father's conceptions and becomes his victim, having his passion and sexual characteristics removed. The critics saw this short story not only as a S.F. one, but also as a mockery, from a scientific standpoint, of certain theories that would later become a nightmare, thus providing: "a virulent and convincing satire on the dangerous fascist theory of race amelioration and dramatically-beyond value, resistance in the face of critics and posterity- probes the lucid, realistic and healthy position of a physician in the face of some aberration which humanity has lived at a certain time in history." [18]

To narrow down The Demiurge to either the categorization of a satire or a S.F. short story is a narrow angle of analysis. The short story represents a new phase for the political drama. The utilization of science to the damage of mankind and the certainty that a scientist can replace God make this short story an outpost of Romanian novellas with political connotations, resembling with "The physicists by Durenmatt" [19] in its intrigue. Just like Faust, Muşatin defies morality, makes a pact in which his own son will fall: the physician transplants his son's genital organs to an elderly person. Other critics claimed to Romanticism the doctor's ability to fuse the real with the fantastic, by embracing revelry and creation. Belonging also to Romanticism is his approach on national history, as an"(…) altar on which he issued canonicals." [20]

Voiculescu's characters take on magical properties, through spells and calling upon magic being able to access a world separated from the perceivable knowledge. This can be seen in the short story In the middle of the wolves (written 2nd May 1947). This time the reasoning main character is a magistrate that collects folkloric elements. To his astonishment, people around him think greatly of him because of his belief of having supernatural powers. The character meets Lupar, the one that used wolves instead of dogs. The influence of the studies attended by the author can be seen in the characterization of Lupar, which resembles the physiognomy of the criminal noted by Cesare Lombroso, Italian physician and criminalist. In order to get closer to this bizarre character, the magistrate admits that he is no stranger to magical practices, as he practiced spiritism. The physician-literate, as Eugen Simion also noted, has the ability to reiterate mythical elements, through refinement, he refreshes them without fatiguing the reader: "V. Voiculescu uses folkloric syncretism which grants him the ability to update the myths without seeming outdated or suggesting their social death and without sociologism and ethnography." [21]

If it is natural to appreciate the pages which send you towards the abyssal psychology thanks to the knowledge Voiculescu gained in his years of medical study, other critics see those writing that forego scientism and appeal to the fabulous as having a real value: "The storyteller Voiculescu finds his own space in those stories in which he steps in not as a psychologist or a social-moralist but as a character in contingency with the unnatural and supernatural." [22] These short stories filled up with an electrifying combination of the profane and sacred, a world which the prose writer does not reveal to the reader but rather lets him discover it, make the author a homo religious. [23]

This effort to reveal the intangible needs to be appreciated even more so knowing that behind the author hides a rational nature, a man of science dominated by practicality and who values systems of rational thinking and deductive judgment: "The positivism of the physician and the rationalism as the love of beings and things of the spiritual man impregnated Voiculescu's stories with the resin that makes objects durable, giving them good clerical fragrance." [24]

Originating from an urban environment, the characters from Voiculescu's short stories are townsfolk which fight a battle of regaining the right to dream, opposing the civilized world which estranges them from their fabulous origins, as the society from which they originate alienates the human being "through the abolishing of humanity." [25] These urbanites fall prey to devouring love, as humanly as possible, and the magic is given off by "beings with a htonic power." [26] Voiculescu remodels reality enriching the means of sensible knowledge: "Sooner a systematic try of apprehending reality through abundancy of sensations, though the equity of perception." [27] As any men of science, Voiculescu is inclined towards explaining in a somewhat scientific manner, in a rational way all deeds that appear irrational." [28] And these explanations are given through the prism of psychoanalysis and psychology.

Treated by some critics as epigrammatic dystopia, Prefrontal Lobo coagulation appears in 1948, meant as a caustic response, a counterweight to the work of the American psychiatrist Benjamin Karpman, entitled Prefrontal Lobes, enemies of humanity. The work references a practice which would end up serving communism through the psychiatric reprogramming of individuals, of creating "new" people and through eugenics. Voiculescu's short story has the merit of constructing itself in a "revelatory text specifically for Voiculescu's harsh perspective and for the pioneering that is represented by his work." [29] Written on the 27th of July 1948, the short story will be printed only later in the journal Transylvania, in its 9th number of the year 1966. Another source of the short story is found in an article signed by Pierre Wertheimer published on the 10th of July 1948 in the French periodical Medical Presses. Voiculescu's short story is not just a S.F. story, even though many a people identified it as such, but also a ridicule of such deviant practices which were used by the Nazi as well.

The new social order is imposed by the Perfect Permanent Presidium of the Nations for Peace and the newborns are subject to an operations that have as a goal the removal of the prefrontal cerebral lobes, whose physiological function is the adjustment of personality. Initially, this intervention has as subjects, those who belong to certain classes, such as: "the sick, anxious, melancholic, suicidal, perfectionists, schizophrenics, mad men, which often times brought them back to normal." [30] The goal was that of neutralizing possible revolutionary elements though the "affective sterilization, aiming especially for the nervous centers of unrest and revolt." For a bigger impact the medic Voiculescu goes through with the description of the inhuman procedure: “But then it was a barbaric procedure. The medic would make two holes in the cranium and then search blindly and cut the roots of the required fibers.” [31] Later they would resort to a less invasive method, automated radio coagulation, which is applied to all people, striving for the numbing of emotions.

To the stupor of all scientists who saw the operation as the perfect way of relieving people from sentiments and emotions, the youth would first present physiological secondary effects such as: “dyspepsia, problems with digestion, lack of appetite, anemia, and especially constipation” followed by reactions that danger the procedure itself: “the disorders took a psychological turn among the youth, the cases of soul sufferings started to stain the once impeccable epithelium of the P.P.P.P.P and the wanderings started to multiply.” [32] People become more and more independent and are surprised by waves of feelings, daring to feel and even love.

The danger proved way greater: people try to be conscious of spirit. Although these manifestations of revolt are harshly punished, scientists try to answer the question if: “not somehow those blasted fibers had awakened some other hidden branch, untouched by the coagulator?” The answer seems to be found in the pineal gland, responsible for sexual impulses and as such it is the next organ which will be annihilated through radio coagulation. In vain, as people continue to be affected by affection among which “dreaming, sloth, glittered with names such as meditation, thinking, the work of inner searching, the inclination toward sadness, jealousy, the fight against competitors for a woman, for a job, all kinds of shortcomings, and most of all the fear for the future, all the metaphysical fears, and the sentimental complications took all kinds of shapes, as never seen before” [33] The search for the source of evil continues and end on the conclusion that the hearth modifies itself physically obtaining a new cerebelous structure because:” (...) it changed not only its aspect, form and weight, but also its histological architecture. It was heavier, redder, more globulous, less muscular, and full of nervous fibers and autonomous ganglions” and more striking is the fact that “in the upper part, on its globe, underneath the exit of the aorta, there were some curly buds that resembled brain buds.” [34] Voiculescu ends his story in a more optimistic way and once again proves the power of his medical studies even in building good quality literature.

Aknowledgement

This paper has been drafted in the period of sustainability within the project entitled “Horizon 2020 – Doctoral and Postdoctoral Studies: Promoting the National Interest through Excellence, Competitiveness and Responsibility in the Field of Romanian Fundamental and Applied Scientific Research”, contract number POSDRU/159/1.5/S/140106. This project is co – financed by European Social Fund through Sectoral Operational Programme for Human Resources Development 2007-2013. Investing in people!

Blockchain technology used in medicine. A brief survey

Horia M. Vîrgolici[1], **Dumitru Ceban**[1], **Raluca C. Răducu**[1], **Victor L. Purcărea**[1]

Abstract: *Blockchain is the technology that allows people to make transactions without intermediaries. Bitcoin was the first cryptocurrency launched. Cryptocurrencies are digital tokens that can be used for transactions. They use cryptography to establish their authenticity and are not linked to a central authority. Blockchain has many advantages for the healthcare industry and can be used in various fields such as: implementation and improvement of electronic patient records, in clinical trials, neuroscience, pharmaceutical industry and research. Its security can help to improve the confidentiality of patient data and can also help secure the supply chain of medicines. The security and transparency of the blockchain will play a crucial role in the medical industry. This will allow companies to register their products and conduct secure transactions. QR codes can also be placed on the back of medicine containers to help customers identify the authenticity of the products they purchase. The exchange of health information through the blockchain will also have various challenges, such as maintaining the confidentiality of patient data. At the same time, due to the different regulations in different countries, it can be difficult to establish an efficient and secure exchange. Unlike other cryptocurrencies, blockchains are usually immutable, which means that the data added in the chain will always remain. This eliminates the risk of data loss.*

Keywords: *blockchain, cryptography, healthcare*

BLOCKCHAIN TECHNOLOGY – INTRODUCTION

Blockchain is the technology behind Bitcoin, an open peer-to-peer value transfer network that has solved the problem of double spending for the first time. With the launch of Bitcoin, cryptocurrencies became the first use of the blockchain. Cryptocurrencies are similar to fiat money, such as dollars or euros, facilitating the exchange of value, but they use cryptographic protocols as a basis for governance, rather than depending on a central authority, such as banks. In recent years, there has been a growing awareness that the blockchain has much more to offer than cryptocurrencies; the blockchain can be an ideal tool for creating solutions based on trust [1].

In Bitcoin, as in cryptocurrencies, a blockchain is a linear chain of blocks or register that applies only to a computer network. A block is a group of validated transactions in the network, and the two consistent blocks are cryptographically linked. However, lately there have been variations in the way the bloc kchain is defined. It is often used as an umbrella term for distributed registry technology used in any peer-to-peer network that tries to solve problems such as double spending. The blockchain can be considered a peer-to-peer distributed registry only for attachments, with immutable and tamper-resistant records. It is important to understand the concept and life cycle of a transaction in order to understand how blockchain works. In the blockchain, a transaction is a state change. For example, a transfer of money from a sender to a receiver is a transaction in which the account balance represents the status. When a new transaction is created, it is transmitted to the network where a mining node (computer) takes over the transaction and composes a block by combining one or more transactions and transmits the block to the network. Each blockchain has a set of rules that determine whether a block created by a miner is valid or not and only valid blocks are added to the chain. For example, a b lock is considered valid and exploited in Bitcoin if it has the correct cryptographic hash. This set of rules forms the basis of blockchain consensus [2].

A blockchain tracks and records transactions and assets. Its

immutability is guaranteed by a network of peer-to-peer computers and not by a centralized authority. Assets can be tangible, such as property and money, or intangible, such as patents and intellectual property rights. Each data blockchain contains a hash (a fingerprint), packets with recent transactions marked in time and a hash of the previous block [3].

Through this architecture, each block is connected in chronological order, and the total number of connected blocks forms a blockchain. It is impossible to modify a block in the middle of the chain, because all the blocks that follow it must be modified at the same time. This mechanism is what provides immutability of data in a blockchain network [4].

Blockchain technology is constantly improving, but it may face some challenges that need to be addressed before it can be adopted in medical applications. The first challenge involves transparency and confidentiality, because all data in a blockchain is public. A second challenge is speed and scalability. Given that the number of transactions in the medical system is enormous, it is clear that a revolution in blockchain technology is needed. A final challenge is that of a possible attack and although this is only theoretical, a viable solution should be found [3].

Blockchain has many benefits for the healthcare industry, such as improving the security of patients' digital medical records, resolving issues related to drug authenticity and traceability of the drug supply chain, and at the same time enabling secure interoperability between healthcare organizations [5].

Every year, the medical industry makes about 30 billion transactions, more than half of which are just faxes, which, despite the high costs, do not always arrive on time in the hands of doctors, leading to an increased mortality rate due to mistakes, administrative, communication of patient-related data [6].

Despite the medical records management system, the lack of a transparent and reliable supply chain leads to huge losses for the industry, as an inefficient supply chain involves the inclusion and sale of counterfeit pharmaceuticals. All of this leads to a substantial loss of money and human lives, but blockchain can solve these problems very effectively, making data interoperable and providing doctors with real-time access to it [6].

Not only the drug supply chain benefits from blockchain technology, but supply chains in general. Counterfeit products are a problem everywhere, especially in the food and pharmaceutical industry. Implementing blockchain technology so that it replaces the traditional supply chain management system is the only way to counteract this situation and prevent the sale of counterfeit pharmaceuticals [7].

Transparency and security are two properties of the blockchain that will play a key role in the medical sector. All companies that want to register their products in the blockchain will have to be reliable, and this aspect will be decided by those who control the private blockchain. Once access is allowed to register their pharmaceuticals in a blockchain, they will be able to store all the data and information about them. Each block of data in the blockchain will be marked temporarily and therefore unchanged. Thus, no entity involved in the transaction of pharmaceutical products, from the company to the retailer will be able to modify the data, so as to introduce counterfeit products. At the same time, the movement of drugs from one entity to another can be tracked in real time, through data stored in the blockchain [6].

QR codes can also be attached to the backs of medicine containers, which provide data about their manufacturers and will help customers verify the authenticity of products, thus preventing them from purchasing counterfeit and therefore dangerous products.

When it comes to managing medical records, no matter how important a patient's medical data is, there is still no effective system for storing them all in one place. Assuming that there is such a system, however, different organizations have different types of systems, which lack interoperability, which makes them useless to some extent. A blockchain network for medical records management can bring order to the medical industry. Regardless of the medical centers and organizations that patients visit throughout their lives, blockchain networks will allow all data to be stored in one place, which allows them to verify and monitor their own information [5].

TYPES AND EXAMPLES OF BLOCKCHAIN

The blockchain can be public or private depending on the level of permission [7], but here we generally classify it on three different levels of granularity.

a)Public blockchain: does not require a permit, and anyone can easily participate and validate transactions. Transactions are public and anonymous / pseudonymous. The blockchain is maintained by the public community, so there is the highest level of decentralized trust. Bitcoin is the pioneer of the public blockchain. Bitcoin, Ethereum, Waves (2018), Dash (2018) and Bitshares (2018) are some examples of public blockchains.

b) Federal blockchain: is a licensed blockchain that operates under the leadership of a group often called a consortium. Predefined consortium nodes control consensus. Transactions may or may not be public. Some examples include R3 Corda (2016), EWF (Energy) (2018) and B3i (Insurance) (2018).

c) Private blockchain: is a centralized licensed blockchain in a government organization. Transactions are validated internally and can be read publicly or not. Private blockchains usually have faster blocking times and can process larger transactions. However, these blockchains are vulnerable to security breaches. The value of the private blockchain can be seen as a reliable transformer in which trust is based on an algorithm rather than an authority. Monax (2018), HyperLedger with Sawtooth (2018), private Ethereum are some examples of private blockchains.

The use of a private blockchain for monitoring and storing personal clinical data is one of the potential examples associated with the Healthcare Data Gateway (HDG) method, introduced by Yue et al.[8]. In this personalized healthcare method, patients are free to access, monitor and manage personal clinical data and healthcare summary, stored on a private blockchain (a centralized database system with restricted access control only for authorized or specific users).

Griggs adopted a private blockchain, based on the Ethereum protocol, to not only facilitate the safe and secure use of medical sensors, but also to eradicate the security risks associated with a remote patient monitoring system. Their blockchain-based strategy can facilitate real-time, remote monitoring, allowing practitioners to track the health of their patients in remote locations while maintaining a secure, safe, and up-to-date patient history [4].

Similarly, Ivan [9] demonstrated an approach to the secure storage of health data by implementing a public blockchain (a decentralized database system with open access control to anyone connected to the network) for encryption. In this method, encrypted healthcare data is stored publicly, developing a blockchain-based personal health record. Their proposed method has allowed patients to have better access to their clinical data, where they can freely access and not only monitor their data, but also contribute to their registration and share them with any associated care agency.

In another study, Chen and colleagues proposed an integrated framework based on cloud and blockchain storage, to manage and share the patient's personal medical data. The proposed scheme could be used to secure and secure the storage and exchange of personal medical data of the patient. The suggested approach is unique in nature, as it gives patients complete access and control over their personal medical data, thus excluding the involvement of any external third party [10].

Wang proposed a blockchain framework, based on parallel execution and artificial health systems, to assess the health status of patients' diseases. The proposed method evaluates the general condition, diagnosis and treatment process of the patient and analyzes the associated therapeutic procedures through parallel executions and computational studies for clinical decision making. The suggested system was tested on real as well as artificial health systems to assess the accuracy of the diagnosis and the effectiveness of the treatment [11].

The researchers developed BloCHIE, a unique blockchain-oriented platform for exchanging health information. The suggested platform assesses healthcare data sharing requirements, mainly for personal healthcare data and electronic medical records, and handles various other forms of data by implementing blockchains in different sources. To validate satisfactory authenticity and confidentiality requirements, they coupled the platform with in-chain and out-of-chain verification processes [12].

In 2017, Shubbar introduced a blockchain-based telemonitoring healthcare framework for the diagnosis and treatment of cancerous tumors in remote patients. The suggested protocol uses smart contracts, along with blockchains that can be widely used to ensure the validity and security of patient data in specialized medical centers as well as in patients' homes [13].

In another study, DermoNet was suggested, a blockchain-based method for assisting dermatology patients through an online dermatological consultation through a tele-dermatology monitoring system (“tele-dermatology”) [14].

ProActive Aging is a blockchain-based platform that helps support the active lives of older people. It should be noted that in extensive medical treatment processes, such as chronic diseases (eg cancer, etc.), surgery, and aging, blockchain technology can be an ideal and well-chosen choice. Moreover, it may be possible for the pharmaceutical industries, drug manufacturers and biomedical researchers to use DNA data stored on blockchains to conduct advanced transnational genomic research [15].

BLOCKCHAIN IN MEDICINE – ADVANTAGES, CHALLENGES, BARRIERS

In Table 1 is shown a SWOT analysis of Blockchain Technology.

Blockchain-based health information exchange will be an interesting use case that requires a balance between confidentiality, transparency and efficiency. Moreover, country-specific regulations will be another obstacle to an exchange that connects several regulatory regions. Because patients have full ownership of their healthcare data in many countries, the blockchain-enabled patient-centered healthcare data model may be an appropriate way to circumvent these regulatory challenges [16].

Blockchain also has use cases in managing the clinical trial process for pharmaceutical research. Recently, the Institute of Electrical and Electronics Engineers Standard Association organized a forum on Blockchain for clinical trials in order to use blockchain to innovate in patient recruitment, ensure data integrity, and make rapid progress in drug development. Scrybe, a blockchain project presented on the forum, enables an efficient and reliable mechanism to accelerate clinical trials and the research process. Among other things, it allows for an easy and transparent framework for legal and ethical validations of the audit process by auditors [17].

Table 1: Clinical characteristics and laboratory results of chronic inflammatory rheumatic diseases groups

Strong	Weak
security there is no need for a trusted third party reliability deals with falsification of immutability records more reliable health system control over healthcare journals	high complexity energy consumption the system is still in the prototype phase the integrity of the information is not guaranteed
Oportunities	**Threats**
safer health systems the patient manages his own data patient records with confidentiality more reliable monitoring of patients at home	resistance of the medical system to change privacy issues medical systems without the ability to support the blockchain structure

Blockchain can be used to manage the consent, data and outcome of a clinical trial in a confident and open manner. Such innovations in the implementation and management of clinical trials are crucial for advances in pharmaceutical research. A lot of clinical trials exceed the budget and deadlines. Competitive sharing of clinical data and studies can accelerate research and discovery. Such data sharing can be enabled with blockchain, using examples of approaches. Moreover, the research aspect of pharmaceuticals is quite broad and goes through the process of drug discovery to device manufacturers and the results of clinical trials. A solution in this spectrum is offered by BlockRX using so-called advanced digital registry technology (ADLT). The general goal is to interconnect the disconnected parts in silos [18].

There are many persistent interoperability challenges. Exchange between different institutions can be an operational challenge and requires significant collaboration between the entities involved. Data sharing agreements, complex patient matching algorithms, governance procedures and rules are just some of the issues that need to be agreed before data exchange can take place [19].

There are also many technical barriers. For example, transactional authentication and the entity must be robust (and repeated for each relationship between entities). Activity and threshold monitoring, together with some detection of anomalies, should also be in place. Finally, data exchange security is essential, and standards for data exchange (eg, Fast Healthcare Interoperability Resources (FHIR) or Confidential Disclosure Agreement (CDA) must also be agreed) [20]. In this context, there has been a recent explosion of energy to improve patients' ability to access their own health data. There is little ambiguity as to whether patients should be able to access their health data - the Health Insurance Portability and Accountability Act (HIPAA) requires covered entities to provide individuals with access to their health data upon request (with certain exceptions, such as would be psychotherapy notes).

The transition to patient-led interoperability will require new processes around security protocols, confidentiality configurations, electronic consent, and governance [21].

All transactions with clinical data have associated verification costs: there is the cost of securing data and complying with regulatory guidelines, such as HIPAA, along with the actual cost of maintaining a primary source of truth, the costs of authenticating different entities and transactions, and also the cost of matching patients (and the implicit cost of non-compliance, measured in clinical errors, manual effort and financial costs). Interoperability efforts absorb these costs through various mechanisms - security and confidentiality personnel, technical assistance, health information management offices, etc. associated with joining and operating a network [22].

Blockchain could provide an important catalyst for improving data exchange, especially for patient-driven interoperability [23].

At a high level, blockchain technology can be considered a platform for digital exchange, where the platform operates without a traditional intermediary. Health data can live in several systems, and data exchange requires many points of collaboration between entities. As interoperability becomes more patient-centered, there is an opportunity to use blockchain technology to facilitate this exchange and give patients greater control over their data [24].

Blockchain allows a centralized and shared mechanism for managing authentication and authorization rules around data. For example, a blockchain may have "Smart Properties" - an entity whose property is managed through a blockchain - to allow a certain form of digital property to have clean ownership. The custodian of the data (e.g., the patient) is clearly represented on the blockchain and can subsequently assign access rules and permissions around their data, allowing for easier sharing [25].

A second way in which blockchain technology could foster patient-driven interoperability is the availability of data. Clinical appointments could be securely broadcast on the network and linked to the patient's anonymous digital identity. Patients could publish their own patient-generated health data in a blockchain network. Such patient-generated health data could provide activity monitoring or other personal health data captured outside the formal health setting, provided that a patient authorizes release [26].

Rapid access to clinical information is a third major way in which blockchain technology could improve interoperability in the patient context. For data (or permissions) stored "in a chain", this is immediately clear - the immutable register clarifies the data permissions and, once this is established, the parties can exchange data. If the data is not stored on the blockchain, but there is metadata about the primary data - for example, calendar or location - then this also allows simplified access. Knowing that a patient has undergone an imaging study at a particular hospital in a given year is helpful, as the investigation may focus on that resource, even if the imaging study itself is not available. In these ways, the blockchain improves the liquidity and availability of data and makes it easier for patients to share their data with other entities [27].

Blockchain's use of the public key infrastructure provides a centralized method of identification - an individual's public key - that can be used to link that patient's records between institutions. If each institution knows a patient's public key and the key was linked to its own internal identifier (for example, the patient linked his public key to the patient's portal account when he registered), then subsequent clinical events broadcast on the blockchain network could includes that public key as a reference for the patient, facilitating patient matching [28].

Because blockchains are usually immutable, the data added in the chain will persist. This reduces the risk of loss, provides an audit trail (for example, in the case of a malicious actor), and ensures that a complete digital history is available to all parties (provided there are adequate access controls) [29].

Although the blockchain could allow for patient-led interoperability, there are several barriers that will require attention. The first barrier is related to the size and volume of clinical data. High volume and high frequency transactions are a cornerstone of clinical data, and the size of clinical data is growing exponentially with modern advances in technology [30].

Another challenge concerns privacy and security. Some implementations of blockchain technology are pseudonyms - the identity is usually hidden behind a public key, but other attributes of transactions are shared publicly. This is problematic for health data [31].

The General Data Protection Regulation adopted by the European Union (EU) includes a "right of erasure" and places health data in a special category of personal data. This further raises additional questions about the intersection of the blockchain, encrypted data and patient privacy, especially in the EU context [30].

Perhaps the biggest barrier to adoption is incentives. Although the legislation requires EHRs (Electronic Health Record) to have patient-oriented APIs, the same is not true for all healthcare data and stimulating institutions to build patient-oriented data connections without financial motivation to do so. Thing will be a challenge - the difference between compliance and true interoperability. For example, although a list of drugs may be a necessary output of a hospital's patient-oriented EHR API, it is not clear that a pharmacy benefit manager must structure and expose each approval or drug transaction without a clear commercial value. Other incentives in terms of data exchange will further strengthen the API economy and lead to greater autonomy of patient data [30].

Table 2: Blockchain network – oportunities and challenges

Oportunities	Challenges
Transparency	Interoperability
Short transaction time	Scalability
Sure	Storage
Cost effective	Social acceptance
Irreversible operations	Requires standardization

BLOCKCHAIN APPLICATIONS IN MEDICINE

Blockchain in Electronic Health Record (EHR)

A prototype called "MedRec" uses distinct blockchain advantages in managing authentication, privacy, integrity, and easy data exchange. It operates on a decentralized records management system and aims to provide patients with a detailed, immutable history and allows easy access to their healthcare information among various treatment providers and institutions [3].

During the implementation of EHR (Electronic Health Record), the sharing of medical data often faces critical limitations, such as loss of control over the data, source of the data, audit and security of the data on the medical data. MeDShare could be used to share medical data and maintain electronic medical records between cloud service providers, hospitals, and health research entities [5].

Dubovitskaya et al. proposed a blockchain-based framework for managing, maintaining and sharing electronic medical records of cancer patients. They have adopted a blockchain technology allowed to access, manage and store encrypted patient data. Such proposed frameworks can be used to practically implement blockchain technology for accessing and managing patient confidentiality and data and patient history in clinical practices [32].

In 2016, Estonia emerged with a global leadership in blockchain technology, when it proposed the idea of keeping millions of private medical records and, at the same time, making them available to healthcare providers and insurance companies [33].

Blockchain in clinical research

In the study proposed by Kevin et al., Ethereum allows for a protocol that provides intelligent contract functionality in the blockchain and is used in parallel with clinical data management systems. The main focus of the study was to address the issue of patient enrollment. The results of the study showed that Ethereum led to faster transactions compared to Bitcoin and, therefore, the derived conclusion proposed the use of Ethereum smart contracts for the transparency of data management systems in clinical trials. Therefore, enrolling patients using blockchains is one of the existing applications of this technology in clinical research [34].

Another research was conducted by Mehdi Benchoufi: A framework was implemented to obtain the informed consent of patients to track and store it in a way that is safe, publicly verifiable and non-falsifiable. They used a blockchain technology to create their workflow [35].

Blockchain in detecting medical fraud

Supply chains are vulnerable and consist of sensitive areas for fraudulent attacks, as they involve a number of moving parties and people. Blockchains provide a secure and secure platform to eliminate this problem and, in some cases, to prevent fraud, by introducing greater data transparency and improved product traceability. Because a blockchain record can only be validated and updated by a smart contract, manipulating the blockchain is not easy [34].

Blockchain in neuroscience

The special task of reading and interpreting brain signals is solved by neural interface devices equipped with several sensitive sensors, computing chips and wireless communications. They read the electrical activity of the brain, which is further deciphered and transmitted to the equipment under control [36]. Compex algorithms and big data will use the blockchain philosophy to store those brain signals on the neural interface. One of the companies that confirms that they will use blockchain technology is Neurogress. By recording user data on a decentralized blockchain, this data becomes "resistant to hacking attacks" and therefore more private. At the same time, the use of blockchain technology makes the Neurogress system "open and transparent to potential users of Neurogress platform services" (https://neurogress.com/).

Digitizing an entire human brain obviously requires an environment in which to keep it, and blockchain technology is raising its head again. One proposal is to store mental files, which would act as blocks of data in personal thought chains, which can be shared in a peer-to-peer network file system that allows historical versions. This type of blockchain thinking is proposed as an input-processing-output computing system, with several features that provide opportunities for artificial intelligence, human improvement and their potential integration. Blockchain allows an interconnected computer network to reach timestamp intervals to validate the source and truth of a register [37].

In the not-so-distant future, we can begin recording our sensory experiences using wearable technology, the current state of brain and nerve implants, biofeedback imaging, and any other sensors that allow a multifactorial fingerprint specific to a particular person's recording of temporal experience. Using these technologies as a starting point, research can be conducted in improving decision-making protocols, learning, recall, and rehabilitation [37].

Blockchain in the pharmaceutical and research industry

In common cases, pharmaceutical companies face the challenges of tracking their products in a timely manner, which sometimes leads to severe risks, allowing counterfeiters to compromise production or invade counterfeit drugs into the system. Consequently, the production and distribution of counterfeit medicines has become one of the major and global health risks, especially in developing countries [25].

During the production, as well as research and development of these drugs, the blockchain could be a technology that fits best, which can be used to evaluate, monitor and ensure the production processes of potential drugs. Recently, Hyperledger launched a medical project using blockchain technology to inspect and combat the production of counterfeit drugs. A digital drug control system (DDCS) could be a sustainable solution for the prevention of counterfeit drugs [38].

Many blockchain-based solutions for intellectual property management have been proposed in the generic space, which can also be applied to innovations in drug development. Bernstein (https://www.bernstein.io/) provides blockchain-based management of digital routes, with timestamping, to protect intellectual property priorities; this feature may be beneficial in collaborative pharmaceutical research. A solution from iPlexus (https://www.innoplexus.com/news/blockchain-and-ai-based-platform-iplexus-to-revolutionize-drug-discovery/) uses blockchain to make any unpublished and published data from drug development studies available for use. Blockchain solves the puzzle of maintaining trust and protecting intellectual property to enable such a revolutionary initiative and framework.

Using a digital drug control system based on blockchain, the major pharmaceutical industries (Sanofi, Pfizer and Amgen) have launched a joint pilot project for the inspection and evaluation of new drugs. Using the blockchain as an approach, it would be possible to aim not only at the production and location of medicines at a given time, but also at improving the traceability of counterfeit medicines, security of the drug supply system and guaranteeing the quality of medicines supplied to consumers or end users [39].

BRIEF CONCLUSION

Blockchain technology is very advanced and secure and could help store data in the medical system and share it much faster between medical institutions.

At a high level, blockchain technology can be considered a platform for digital exchange, where the platform operates without a traditional intermediary. Health data can exist in several systems, and the exchange of data requires many points of collaboration between entities. As interoperability becomes more patient-centered, there is an opportunity to use blockchain technology to facilitate this exchange and give patients greater control over their data.

Of course, there are certain barriers and challenges that need to be overcome.

Bucharest mobile military hospital – response to the COVID-19 pandemic

Florentina Ionita Radu[1,2], Ileana Mariana Mates[1], Valeriu Gheorghita[1,3]

Abstract: *The idea of using mobile hospitals - a fully functional hospital is a system with a high degree of complexity - in case of a pandemic crisis, is not new, but shows how much they are needed.*

Solutions belonging to the category of mobile architecture are increasingly common, technical and logistic difficulties are solved in more perfect way. This applies mostly to objects with simple layouts and functional relationships, with relatively little technical equipment. In the case of healthcare facilities there are several factors increasing the difficulty: multitude of functional connections, sanitary requirements, technical equipment, and internal infrastructure.

The Romanian military and civilian specialists from Bucharest Central Military Emergency University Hospital (SUUMC) showed that is possible to build a hospital as a modular and mobile structure in order to fight COVID 19, but the strategic actions and the effort needed to organize and run mobile hospital far exceeds the expenditure, protocols and specialized M.D.s necessary to run the stationary hospital.

Keywords: *mobile hospitals, COVID-19, strategic actions*

INTRODUCTION

SARS-CoV-2, the causative agent of COVID-19, is a newly discovered coronavirus. It is transmitted through respiratory droplets and direct contact; other modes of transmission (i.e. airborne and digestive) have been proposed, but they are still under investigation. The average incubation period is estimated at 5 to 6 days, ranging from 1 to 14 days [1]. There is currently no approved specific treatment or vaccine against COVID-19.

Business-as-usual service delivery approaches are not sufficient to respond in the fight against COVID 19, once cluster of cases or widespread community transmission is registered and superior capacity will be needed.

While World Health Organization (WHO) advises that aggressive measures to find, isolate, test, treat and trace are the best ways to stop the spread of this virus, public health interventions to "flatten the curve" may slow transmission and mitigate peak capacity needs. Modelling studies point to the impact of nonpharmaceutical interventions (NPIs), such as physical distancing, school and university closures, banning of mass gatherings, and remaining indoors, on spreading the number of cases over a longer period to give health systems the opportunities they need to cope with caseloads [1, 2, 3, 4]

These models have helped to reinforce the message from WHO about the implementation of such measures, alongside widespread testing, to detect cases and break chains of transmission. In addition to these measures, phased plans for creating surge capacity in acute and intensive care will help respond to COVID-19 cases while maintaining essential health services.

Surge capacity is the ability of a health system to manage a sudden and unexpected influx of patients in a disaster or

---

[1] Carol Davila University Emergency Military Hospital, Bucharest, Romania
[2] Titu Maiorescu University, Bucharest, Romania
[3] "Carol Davila" University of Medicine and Pharmacy, Bucharest Romania

emergency situation.

Surge capacity can be created from intrinsic and extrinsic resources. The former covers all local resources that can be used for the response, while the latter involves leveraging resources from outside the affected area (across geography or across specialty).

As the COVID-19 pandemic necessitates both in tandem in all countries, this note covers both these aspects together. Creating surge capacity involves a comprehensive approach linking the 4 S's of surge capacity: space, staff, supplies and systems. [5]

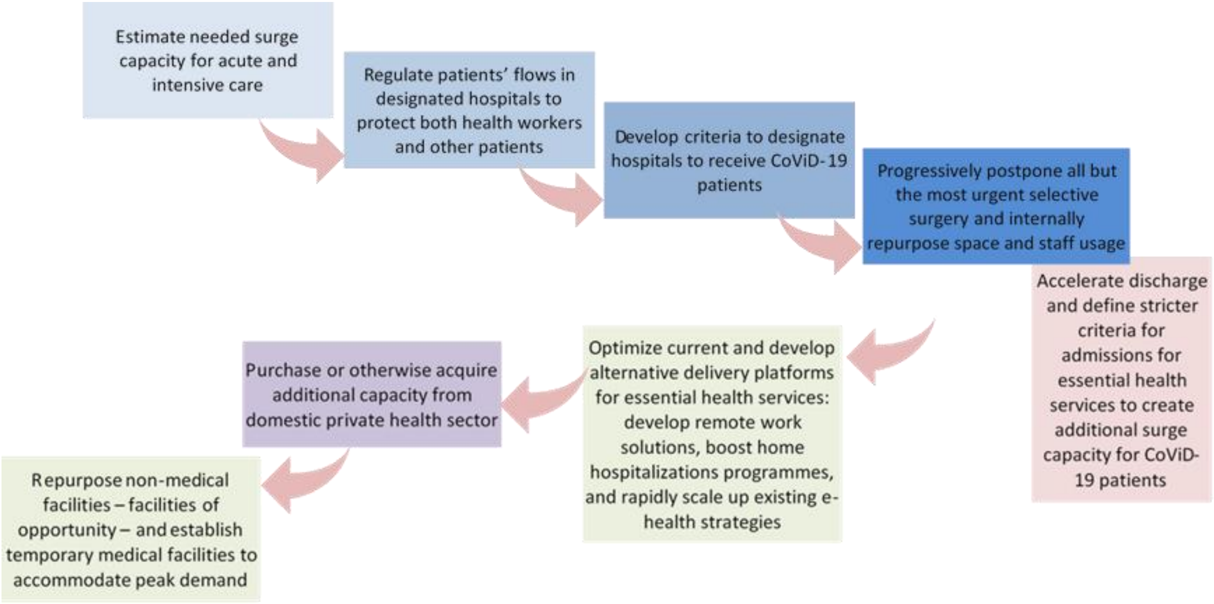
RECOMMENDATIONS AND STRATEGIC ACTIONS

In the following, are presented the recommendations and strategic actions to activate surge capacity in line with the 4 S's drawing on past experiences in emergencies and on the emergent experiences of world countries in the COVID-19 response.[6]

Strategic action 1. **Create and activate a stepwise plan to expand physical space to care for COVID-19 patients respecting infection prevention and control protocols**.

This action requires the following steps, and is schematically presented in the Figure 1.

Figure 1: Necessary steps for strategic action 1

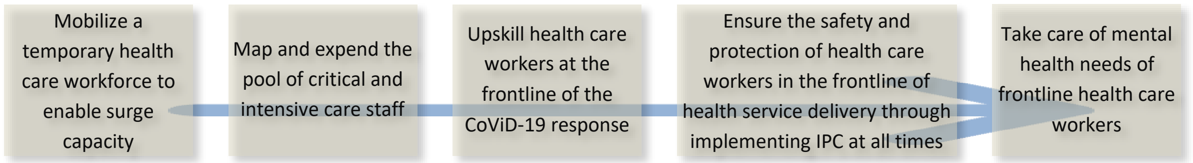


Estimate needed surge capacity for acute and intensive care
Regulate patients' flows in designated hospitals to protect both health workers and other patients
Develop criteria to designate hospitals to receive CoViD-19 patients
Progressively postpone all but the most urgent selective surgery and internally repurpose space and staff usage
Accelerate discharge and define stricter criteria for admissions for essential health services to create additional surge capacity for CoViD-19 patients
Optimize current and develop alternative delivery platforms for essential health services: develop remote work solutions, boost home hospitalizations programmes, and rapidly scale up existing e-health strategies
Purchase or otherwise acquire additional capacity from domestic private health sector
Repurpose non-medical facilities – facilities of opportunity – and establish temporary medical facilities to accommodate peak demand

Strategic action 2. Identify the health workforce available for surge capacity demands, and repurpose and upskill for rapid deployment to meet surge capacity needs

The steps necessary for this strategic action are depicted in Figure 2.

Figure 2. Necessary steps for strategic action 2



Mobilize a temporary health care workforce to enable surge capacity
Map and expend the pool of critical and intensive care staff
Upskill health care workers at the frontline of the CoViD-19 response
Ensure the safety and protection of health care workers in the frontline of health service delivery through implementing IPC at all times
Take care of mental health needs of frontline health care workers

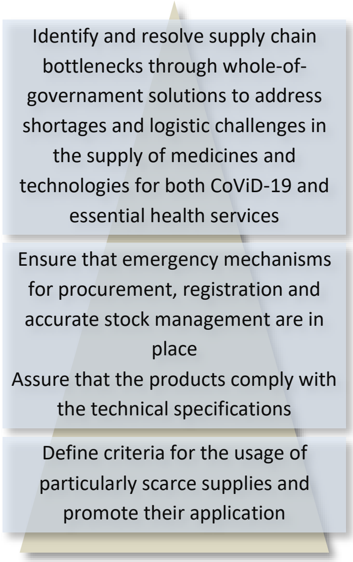
Strategic action 3. Ensure adequate supplies to support surge in demand

The necessary steps for strategic action 3 are presented in Figure 3.

Strategic action 4. Establish systems to manage and align policies to meet surge in demand

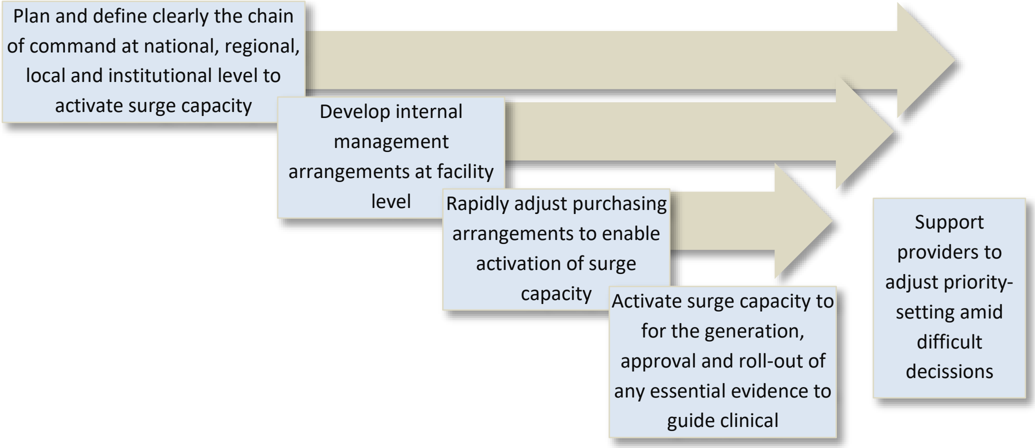
The steps that are necessary for strategic action 4 are mentioned in Figure 4.

Figure 3: Necessary steps for strategic action 3



Identify and resolve supply chain bottlenecks through whole-of-government solutions to address shortages and logistic challenges in the supply of medicines and technologies for both CoViD-19 and essential health services
Ensure that emergency mechanisms for procurement, registration and accurate stock management are in place
Assure that the products comply with the technical specifications
Define criteria for the usage of particularly scarce supplies and promote their application

Figure 4: Necessary steps for strategic action 4



Plan and define clearly the chain of command at national, regional, local and institutional level to activate surge capacity
Develop internal management arrangements at facility level
Rapidly adjust purchasing arrangements to enable activation of surge capacity
Activate surge capacity to for the generation, approval and roll-out of any essential evidence to guide clinical
Support providers to adjust priority-setting amid difficult decissions

THE ROL 2 MILITARY HOSPITAL AT THE ANA ASLAN INSTITUTE IN OTOPENI, NEAR BUCHAREST – A CASE STUDY

The ROL 2 military hospital was installed at the Ana Aslan Institute in Otopeni city, near Bucharest, to support the Romanian government as a response to the Covid-19 pandemic. The ROL 2 was declared operational on Saturday, March 28, in the presence of President Klaus Iohannis and Prime Minister Ludovic Orban, the Ministry of Defense announced.

Once accredited by the Ministry of Health, the ROL 2 hospital will operate as an external facility of the Central Military Emergency University Hospital (SUUMC). The mild and medium cases of COVID-19 will be admitted and treated in this medical facility (Figure 5).

Figure 5: The ROL 2 first medical team

The ROL 2 mobile military hospital operate as a stand-alone entity (as in the American solutions), or in conjunction with the whole hospital – Bucharest Central Military Emergency University Hospital (but still autonomously, as in European solutions). These two variants are taking into account organisation of space or technological line flow. The difference between the two models comes down to one important aspect: in the European pattern patients' flow is unidirectional, almost linear, from the entrance of the patient to the segregation area (TRIAGE), through diagnostic and treatment facilities ending at the hospital bed wards). This is due to the principles of Emergency Department (DE) operation. ED is an integral part of the hospital and at the same time it is an emergency path of hospitalization. The American ED is more autonomous unit, operating often as an outpatient clinic compared to European standards: the TRIAGE and central nurse station become the most important areas of the ED. Other functions of the ED are grouped around the focal point of the nurse station. The flow of patients through the ED is less structured, without clearly separate movement paths, always through the nurse point.

In the case of building a mobile military hospital there are several factors increasing the difficulty: multitude of functional connections, sanitary requirements, technical equipment, and internal infrastructure, which includes both the military and civilian objectives.

The mobile military hospital is built as a reaction to disasters, both natural and those resulting from human factor, for "emergency" (acute and crisis situations) activities. An emergency medicine, no matter of the form of its organisation, is a set of medical actions, serving a life rescue.

The technical solutions are related to 2 terms: modularity and mobility. Modularity should provide a construction of possibly most numerous and diverse structures of various purposes. Mobility is to ensure a solution which enables the module (typical commodity container) to be loaded and transported by standard ways: truck or a ship, or even air-borne.

For this achievement, the management of the Bucharest Central Military Emergency University Hospital (SUUMC) conceived a procedure which has been developed to support hospital preparedness for the management of COVID-19 patients, based on European Centre for Disease Prevention and Control recommendations [7]. The procedure started with the procurement and stock management. A procurement procedure to acquire the necessary materials and supplies was activated on short notice and alternative suppliers have been identified. The acquisition team took into account that if main suppliers should run out of stock (especially for personal protective equipment (PPE)) a buffer stock of key supplies has been acquired (e.g. for hand and respiratory hygiene, PPE, isolation, ICU supplies, mechanical respirators). A procedure to monitor and regularly update the inventory and a stock inventory have been conducted. In order to avoid misuse or overuse, a plan was developed to keep track and custody of key supplies (e.g. PPE, ventilators, cleaning and disinfection material, alcohol solution etc.).

The maximum facility capacity, including the maximal number of ICU beds, mechanical ventilators, bins for infectious waste, and the required human resource capacities (M.D.s, healthcare workers and cleaning personnel) and supply capacity have been calculated.

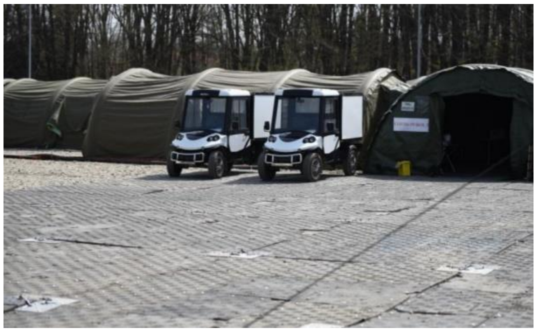
Storage facilities which meet all demands with respect to temperature, humidity, cold-chain, logistics etc., for additional stock have been identified, also a proper amount of cleaning and disinfection products shown to be effective against coronaviruses is available. A procedure to ensure that equipment is in perfect working order and can be quickly replaced whenever necessary was developed.

All staff, healthcare and non-healthcare workers, have been informed and trained on the following topics: Case definitions, Hand and respiratory hygiene, How to use PPE's and know the documents outlining the procedures, Triage procedures, Placement and movement of patients in isolation, Internal and external communication lines and rules, Sick-leave policy and what to do if staff members show symptoms and Security plan.

Procedures for patient prioritization (e.g. triage, discharge criteria, triggers to postpone elective hospitalizations or interventions) are in place A patient' system before they arrive at the hospital is in place: phone/email/telemedicine services are in place for possible cases.

A procedure for the cleaning of the rooms on a regular basis and after a patient's discharge has been established.

Figure 6: The ROL 2 mobile military hospital – general view



The ROL2 mobile military hospital, made up of medical tents and containers (Figure 6) is intended for the triage, diagnosis and hospitalization of patients confirmed with COVID-19. The structure of the hospital is composed of two parts: the medical and the administrative part. The medical part is structured in the following sections/laboratories/

compartments:
- Emergency Room Unit (ERU) with 20 beds
- Infectious Diseases Department (IDD) with 120 beds
- Intensive Care Unit (ICU) with 24 beds
- Imagistic Laboratory
- Medical Analysis Laboratory
- Pharmaceutical point

The hospital was equipped with medical equipment necessary for the diagnosis and treatment of patients with COVID-19, as follows: necessary RT-PCR for the identification of COVID-19, biochemistry analyzer, mobile radiology apparatus, ultrasound device, oxygen concentrators, pulse oximeters, laryngoscopes, intermittent mechanical compression devices, patient heating system, trolleys for the storage of sanitary materials and medicines, , air purification devices, wheel sprayers for car-trucks disinfection.

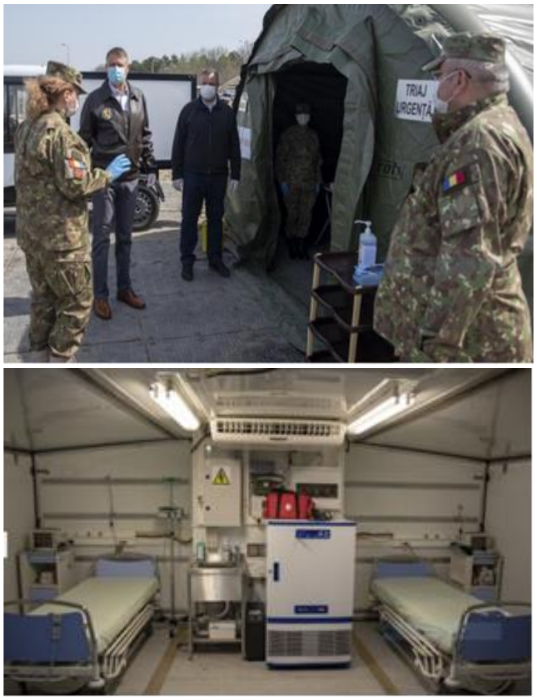
The Intensive Care Unit (ICU) was equipped with specific beds, secretion aspirators, oxygen pumps, automatic syringes with related stations, mechanical fans, and monitors for monitoring vital functions. Very important is the fact that telemedicine system has been installed with video cameras for the monitoring of patients, so the medical staff can keep them under observation, with minimal contact.

The Emergency Room Unit (ERU), adjacent to the patient triage area, is equipped with 8 beds and a stationary area featured with 6 compartments of 2 beds for patients waiting for lab results and for carrying out complementary investigations (interdisciplinary evaluations, imaging investigations). If the number of patients presented is greater than the capacity to take in the ERU, there are two waiting areas for patients featured with chairs located at a distance of at least 1 meter, in an adjacent tent (Figure 7).

The Infectious Diseases Department (IDD) is designated for the admission of patients confirmed with COVID-19. The section is provided with 120 beds equally distributed in 30 individual reserves with own sanitary group. Each reserve is provided with medical equipment and equipment for the permanent monitoring of patients, with the possibility of ensuring the oxygen requirement to patients who do not meet the criteria for admission to the intensive care unit. All IDD rooms are sterile environments; all personnel wear protective clothing (scrubs), shoe covers, masks, caps, eye shields and other coverings.

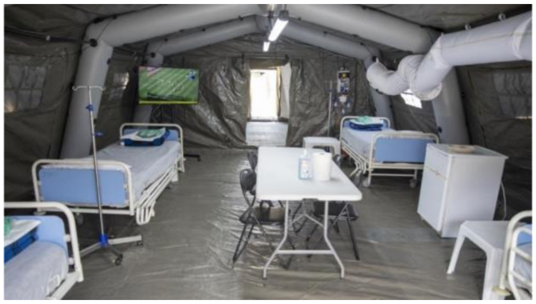
The inventory for 1 IDD reserve (Figure 8) includes: 4 beds, disposable linen, 1 TV set, 1 telephone and equipment for the medical supervision of patients (nurse-call system), 1 refrigerator, 4 stands of infusion, 1 acute care physiologic monitoring system (comprehensive patient monitoring systems that can be configured to continuously measure and display various parameters via electrodes and sensors connected to the patient), 4 pulse oximeters, 1 treatment table, 4 bedside tables. Lingerie is changed daily and whenever necessary.

Figure 7: The Emergency Reception Unit (ERU)



Upon admission to the IDD, each patient will receive a disposable kit containing: 1 disposable pajamas, 1 pair of disposable slippers, 1 toothbrush and toothpaste, 2 absorbent fields (towels) size 90/140 cm^2. These materials will be later distributed, whenever appropriate.

Figure 8: IDD reserve

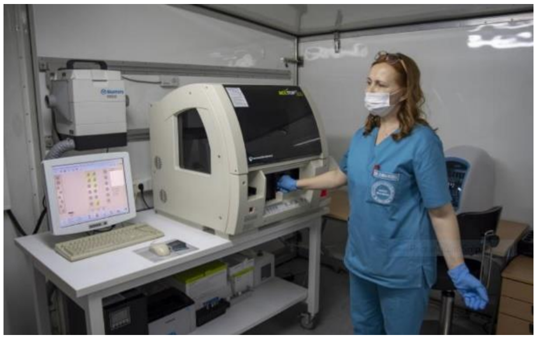


The medical part also comprises:

- **The Intensive Care Unit** (ICU) is undergoing an arrangement with 24 beds and it is located in the annex building of the ROL 2 hospital. Patients with severe respiratory disorders cannot be properly treated in tents, as they must benefit, for a certain period of time, of special care and connection to mechanical fans.

- **Two own laboratories** (Figure 9) where diagnostic tests (RT-PCR) and respectively hematological and biochemical investigations (complete blood count, CBC (hemoglobin), Erythrocyte Sedimentation Rate (ESR), coagulation test, myoglobin, D-Dimer, blood chemistry tests including Ferritin, troponin test, procalcitonin (PCT), presepsin (P-SEP), HBV, HCV, HIV Screening Tests, detection of SARS CoV 2 with RT-PCR) will be performed.

Figure 9: Laboratory for diagnostic tests (RT-PCR) and hematological - biochemical investigations



- **Imaging laboratory** provided with a mobile radiology device and Computer Tomography machine.
- **Pharmaceutical point** (Figure 10) where antiviral drugs necessary for the treatment of patients confirmed according to the national protocol adopted at the level of the Ministry of Health and taken over by this structure will be available.

Figure 10: Pharmaceutical point

At the ROL 2 hospital level, the functional circuits with the delimitation of the red and green areas, are ensured by providing separate flows for patients and medical staff, with rooms for equipping the medical and auxiliary staff and separate rooms with their own sanitary for undressing.

The sections and compartments of the ROL 2 hospital are computer interconnected between them and the command point, as well as with the computer network of S.U.U.M.C "Carol Davila".

The payroll comprises a total of approximately 270 positions distributed over each structure. For the operationalization of the ROL 2 Hospital, the personnel will be provided from the human resources of the S.U.U.M.C. and partly from the Medical Directorate.

The work program of the staff is structured on each separate compartment, in 12-hour shifts, over a 7-day cycle and is provided by working medical corps, made up of doctors, nurses, stretches. After this period of 7 days, the work team enters the period of self-isolation for a period of 7-14 days, a necessary measure for both the rest and the physical and mental recovery of the personnel and for the epidemiological supervision. The activity will be continued by other working medical corps, following the same structure.

At the entry and exit of the 7-day work cycle, the entire workforce will be clinically evaluated and the diagnostic test using RT-PCR for COVID-19 will be performed. Also, the staff will be tested as needed if it becomes symptomatic during the activity.

The work program is structured as follows:

- 7 consecutive days with 7 days rest for doctors and 14 days for nurses, nurses, stretches and medical administrators;
- Daily, there will be two shifts (day and evening) at 12 hours intervals; the ranges are from 08:00 – 20:00, respectively 20:00 – 08:00;
- Each 12-hour work program is provided by separate working medical corps.
- The structure and work schedule for a 7-day cycle of the IDD
- 2 specialist/consultant doctors (infectious diseases and pneumology or internal medicine);
- 6 residents (infectious diseases – 2 and internal medicine – 4);
- 12 nurses (also includes the head nurse);
- 4 orderlies;
- 2 stretches.

The procedure described may not be applicable to all military or civilian hospitals and may need to be adapted to the specific characteristics of the hospital, the individual national health system, legislation and community where the hospital is located.

“Today I visited the ROL 2 Military Hospital, a medical facility made in record time by the Army and the military medical personnel. Romania is prepared to cope as well as possible with this epidemic and I assure you that we will continue to

take all necessary measures to be even better prepared," Klaus Iohannis (Figure 11) said after visiting the hospital. [9]

Figure 11: The Romanian President Klaus Iohannis and Major General Assoc. Prof. Florentina Ioniță-Radu MD, PhD at the inauguration of the ROL 2 military hospital installed at the Ana Aslan Institute in Otopeni (Photo: Presidency.ro)

The same ROL 2 military hospital was deployed in 2015 when it was supposed to treat potential Ebola infection cases. It was also used in NATO military exercises in 2019, including Vigorous Warrior – the biggest medical military exercise ever organized by NATO, which was hosted by Romania.

"*I have entrusted the supreme ally commander of Europe with the task of coordinating all the means of supporting, coordinating and directing all the excesses at national level to the allies who need support at this particular moment, a first step taken by NATO, at this moment, is to provide the logistics of allies who need support in the fight against the coronavirus pandemic*." said Mircea Geoana, NATO Deputy Secretary General. [10]

CONCLUSIONS

The set up of the mobile military hospital installed at the Ana Aslan Institute in Otopeni, near Bucharest, to support the Romanian government as a response to the Covid-19 pandemic complies all the health requirements regulations defined by the National Authority of Quality Management in Health (Autoritatea Naţională de Management al Calităţii în Sănătate – ANMCS) throughout specific accreditation standards for medical units.

Further studies are necessary in order to determine the Covid-19 pandemic amplitude actions to end it, and future research projects destined to cover the need and development of these mobile hospitals, which involve a multitude of functional connections, sanitary requirements, technical equipment, and internal infrastructure is necessary.

Note

The ICU is arranged in the annex building of the ROL 2 hospital. Patients with severe respiratory disorders cannot be properly treated in tents, as they must benefit, for a certain period of time, of special care and connection to mechanical fans.

Burnout syndrome in the Emergency Department of the Central Military Emergency Hospital before and during the COVID-19 pandemic

Florea Costea[1], Mihai Sălceanu[1], Iulia M. Staicu[2], Alexandru G. Andreescu[3]

Abstract: *Introduction: Public interest in burnout has grown recently in developed countries, as has media coverage. Burnout has been a topic of scientific research in recent years for psychologists and sociologists alike. They have published numerous articles on the identification and classification of burnout syndrome.*

The medical staff is quite exposed to burnout because they often experience strong emotions such as the desire to treat or save their patients, fear of failure, occasional failures in the treatment of diseases.

Materials and methods: This study aims to highlight the impact of the burnout syndrome in the Emergency Department of the Central Military Emergency Hospital during the COVID-19 pandemic, by conducting a comparative study based on the results of a questionnaire applied to the medical staff before and during the COVID-19 pandemic.

Results: The study interviewed 65 participants aged between 20 and 60 years. They had to anonymously answer 16 questions marked with scores from 1 to 4.

Comparing the results highlighted by the questionnaire, applied before the COVID-19 period, with those obtained in the questionnaire applied between May and June 2020, we noticed an increase in the level of burnout in all categories interviewed during the pandemic.

Conclusions: In conclusion, the high level of contagiousness and the lack of a vaccine or treatment against SARS-CoV2 infection are additional concerns for burnout syndrome among healthcare professionals.

Keywords: *COVID-19, burnout syndrome, healthcare professionals*

INTRODUCTION

What is burnout?

The term "burnout" appeared 25 years ago in the United States. One of the first scientific descriptions of burnout syndrome was made by the psychoanalyst Freudenberger who described it as manifesting polymorphic symptomatology that fluctuates in degree from person to person [1]. In 1981, Maslach introduced a far-reaching definition and psychometric tool for assessing burnout syndrome, which is still the most commonly, used today, The Maslach Burnout Inventory [2].

An alternative to assessing the burnout syndrome has become "The Oldenburg Burnout Inventory: A Good Alternative to Measure Burnout (and Engagement),"

[1] Carol Davila Central Military Emergency University Hospital, Bucharest, Romania
[2] Institute for Military Medicine, Bucharest, Romania
[3] “Titu Maiorescu” University, Bucharest, Romania

published by Prof. Dr. Evangelia Demerouti in 2007 at the Utrecht University in the Netherlands. She is well-known for her research in the field of occupational burnout and introduced this method to quantify the burnout syndrome based on two proportions: exhaustion and disengagement. Her annotations in the 2008 article define exhaustion as being a repercussion of intense and prolonged physical, affective, and cognitive pressure such as the long-term effects of protracted tedious job demands. On the other hand, she noted that disengagement can be identified as a breakaway, chiefly from work, the activity, or the object of the said workplace, for example, becoming uninteresting, challenging, or even disgusting [3].

Burnout has been a topic of scientific research in recent years for psychologists and sociologists alike. They have published numerous articles on the identification and classification of burnout syndrome, but the major problem that remains is that there is no generally accepted definition of burnout. Identifying potential causal factors and separating them from other health disorders is difficult, which represents the main reason why it is difficult to identify a generally valid definition. Therefore, an interdisciplinary approach would probably help a broader understanding of burnout syndrome, which has become a common pathology in modern occupational medicine (Figure 1).

Although hard to systemize and cut down to a single phrase definition, studying the medical literature, we found it is widely accepted that burnout is a syndrome defined by emotional debilitation, a loss of the sense of self, and personal accomplishment. Symptoms that may be identified in medical staff are anxiety, impatience, mood swings, and depression. Moreover, physical health may be impaired, with manifestations such as disseminated aches and pains, digestive problems, and increased cardiovascular risk. All in all, these symptoms are not specific enough to guide a person in seeking help [4].

Burnout syndrome was found more widely in careers that involve personal contacts with other people, specifically those that imply a high level of demand and pressure on the worker. Even though the medical staff represents the majority of those affected by burnout, it is important to note that occupational groups such as advocates, teachers, or human resources have been reported to also be prone to this syndrome [5].

Specific psychiatric literature has not yet classified burnout, for example in the “Diagnostic and Statistical Mental Disorder, 5th edition (DSM-5) [6]. In some European countries, such as Sweden, symptoms of burnout represent a justification for sick leave. Proof of the developing awareness of this syndrome is its inclusion as health altering and contact with medical services in the 10th revision of the “International Classification of Diseases” [7] (ICD-10) where burnout is coded Z73.0 and characterized as a state of vital exhaustion [8].

Psychosomatic disorders, suicide

Burnout on medical staff

In the last few years, there has been an increasing emphasis on the impact of professional activity regarding the health of medical staff, with numerous studies showing that medical staff is more affected by burnout syndrome than staff in other fields.

Healthcare workers have always had an active, routine life and have assumed from the beginning of their careers that they will have to make personal sacrifices for the good of patients. Besides, the daily decisions on which patients' chances of healing or their chance at life depend on them.

The factors that manifest a strong emotional impact on the medical staff have recently multiplied: there has been a risk of malpractice, the swift evolution of technology that requires continuous professional training (in detriment of free time), increased administrative burdens correlated with reduced consultation time for each patient.

Table 1: Factors that may influence a doctor's well-being [11]

Categories of factors	Examples
Chronic fatigue	Excessive workload Sleep deprivation Constant access demands (eg. Electronic availability) Decresed personal time
Perceived threats	Malpractice lawsuits Medical error Reduce compensation Research funding climate
Loss of autonomy	Practice environment Time to interact with patient constrained
Inefficiencies	Administrative requirements Lack of support staff Practice organization
Balancing needs	Suboptimal integration of work and life responsibilities Clinical service requirements and additional demands (teaching or administration)
Chronic stress	Work pace Practice setting
New technologies	Electronic medical health records Keeping up with technological advances in the practice
Physician factors	Perfectionism Internal drive and ambition Negligence regarding personal health and well being

All the aforementioned factors create an environment in which the practitioner is exposed to multiple high-stakes decisions, rendering the situation into a physically, psychologically, and emotionally stressful experience. As a consequence, medical professionals may show signs of emotional distress and avoidance behavior. Furthermore, long-term absence may be seen, with an alarming level of skill drain, leading to economical strain. The quality of medical services may also be affected [10].

All these factors have led to an increase in the number of medical staff exposed to burnout syndrome (Table 1).

The global effects of COVID-19

Coronavirus is a family of viruses that can cause diseases such as respiratory viruses, severe acute respiratory syndrome (SARS), and Middle East respiratory syndrome (MERS). In the winter of 2019, a new member of this family, SARS-CoV-2, was identified as originating in China, more precisely the source of the outbreak was the municipality of Wuhan. The disease caused by this virus is called COVID-19. In January of 2020 isolated cases were reported in some European Union states. By the end of February 2020, Italy reported an important increase in COVID-19 cases. [12] Following the accelerated evolution and spread of SARS-CoV2, the World Health Organization (WHO) declared COVID-19 as a global pandemic.

The rapid spread of SARS-CoV-2 globally had a strong psycho-emotional impact among the population, developing an increased level of stress and anxiety. The most affected by the psychological effects were the vulnerable groups directly involved in this infection, the elderly, the people from the placement centers, the staff in the front line. At the same time, this increase in the level of stress and anxiety was accentuated by the strict measures applied to prevent and combat the disease (quarantine, isolation, change of daily routine). Adding up to the ambiguity experienced by the population was a storm of catastrophic and sometimes sensational bits of information that was spread through various forms of media consumption platforms, rendering the citizens uncertain and helpless while sustaining a sense of distrust towards official information [13]. All these factors have led to an increase in the number of people affected by depression, an increase in alcohol and drug use, and an increase in the number of suicides, while in the long run post-traumatic stress disorder (PTSD) is anticipated (Figure 2) [11, 14].

Effects of COVID-19 on medical staff

The COVID-19 pandemic generated a major health crisis globally, which led to the reorganization of health services, with an emphasis on emergency services, intensive care units, and infectious disease and epidemiology departments.

At the national level, several support hospitals have been declared, for example in Bucharest, support hospitals – phase II – such units are the Central Military Emergency University Hospital-ROL2-COVID-19 Military Camp Hospital, Marius Nasta Institute of Pneumophtisiology.

Medical personnel is constantly exposed to the risk of becoming infected with viruses, bacteria, or parasites. This risk is accentuated during a global pandemic, thus increasing the predisposition for the development of burnout syndrome in the case of the health personnel. The fast pace of work, special conditions (requiring special protective equipment), the multitude of uncertainties since the beginning of the pandemic regarding the mode of transmission, the treatments, and prevention methods have created an additional level of stress and anxiety for the medical staff.

Population

Medical teams in the emergency department were also at increased risk of contamination because at the time a patient was presented to the emergency department; health care staff could not tell if he or she was infected with COVID-19 until the PCR test was performed. This situation together with spending an increasing number of hours in the hospital to provide the best care to patients has led to a strong social and psychological impact on the medical staff.

Thus, many of those working in the health system during this period experienced conditions such as anxiety, fear, social marginalization, depression, and post-traumatic stress. Therefore, if we take into account the definition of burnout which involves long-term exposure to stress and exhaustion at the workplace, we can explain the increase in the intensity and impact of burnout syndrome during this period of medical staff.

OBJECTIVES

Healthcare workers are extremely vulnerable to stress and exhaustion due to the characteristics of the work performed. Numerous studies conducted so far highlight the presence of psychosocial impairment of health professionals in many countries, thus becoming a global problem. Furthermore, they may be exposed to additional factors in the work environment: that is physical, biological, chemical factors. The COVID-19 pandemic is an additional element that has amplified the risk of burnout syndrome among medical staff.

This study aims to highlight the impact of the burnout syndrome in the Emergency Department of the "Dr. Carol Davila” University Central Military Emergency Hospital during the COVID-19 pandemic, by conducting a comparative study based on the results of a questionnaire applied to medical staff before and during the COVID-19 pandemic.

MATERIALS AND METHODS

While writing the current study we have used the “Oldenburg burnout inventory scale” and the statistical data which have been obtained through a survey carried on the medical staff within the ER unit of the Central Military Emergency University Hospital "Dr. Carol Davila” in the May-June 2020 timespan.

The psychometric tool used in this situation – to assess the syndrome’s impact on the ER medical staff – has consisted of the “Oldenburg burnout inventory”. This involves a set of 16 queries (8 with a direct answer, the other 8 including indirect answers) which aim at measuring the burnout and professional involvement levels.

The clinical method was based on the application of a questionnaire to the medical staff from the Emergency Unit of the Central Military Emergency University Hospital „Dr. Carol Davila ”between May and June 2020.

The analytical method was used to interpret the results thus obtained. The data thus obtained were analyzed and shared with those resulting from the application of the same questionnaire in the period before the COVID-19 pandemic. For the statistic, we used the EpiInfo program and Excel.

RESULTS

The study interviewed 65 participants aged between 20 and 60 years. They had an anonymous answer to 16 questions marked with scores from 1 to 4 (1- Totally agree, 2- Agree, 3- Disagree, 4- Total disagree) (Table 2).

Table 2: Oldenburg Burnout Inventory in ER unit of the Central Military Emergency

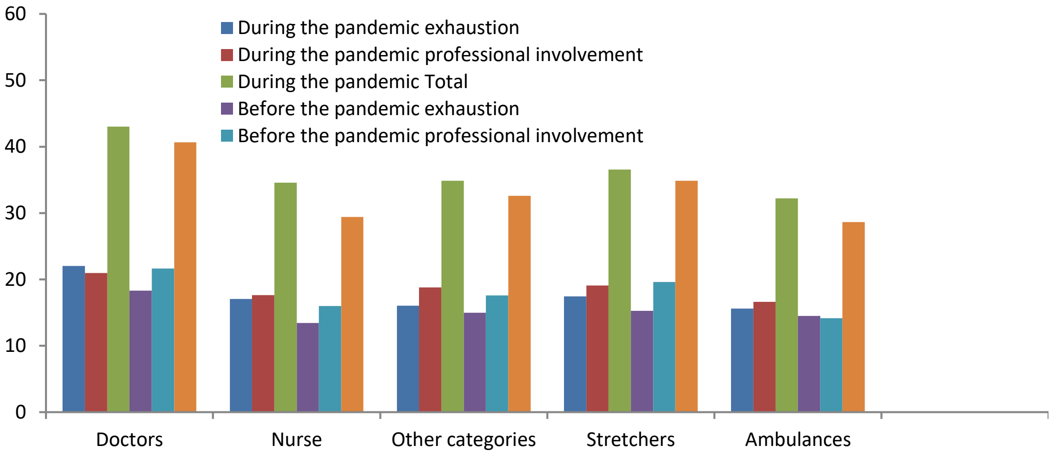
	Questions	Totally agree	Agree	Disagree	Totally disagree
1	I always find new and interesting aspects in my work.				
2	There are days when I feel tired before I get to work.				
3	It happens more and more often that I speak badly to people.				
4	After the program, I need more time than before to relax.				
5	I can easily cope with the pressure at work.				
6	Lately, I tend to think less about work and do things more automatically.				
7	I find the service a positive challenge.				
8	During work, I often feel powerless.				
9	Over time, I may become disinterested in what I am currently working on.				
10	After work, I have enough energy left for my favorite leisure activities.				
11	Sometimes I feel disgusted with my tasks at work.				
12	After the program, I usually feel worn out and tired.				
13	I wouldn't see myself working on anything other than what I'm doing now.				
14	Usually, I can dose my work well.				
15	I feel more and more captivated by my work.				
16	When I work, I usually feel full of energy.				

In the questionnaire applied before the COVID-19 pandemic, 65 participants aged between 21 and 60 years were interviewed, of which 25 women and 40 men, distributed on the following personnel categories: 12 doctors, 31 nurses, 5 people belonging to other categories, 6 ambulances, and 8 stretchers.

At the same time, in the questionnaire applied between May and June 2020, 66 medical staff aged between 21-60 years participated, of which 32 women and 34 men, distributed as follows: 22 doctors, 19 nurses, 11 stretchers, 3 ambulances, and 5 people belonging to other categories.

We observe that in both questionnaires the doctors obtained the highest average scores of the burnout level, both in terms of the component of emotional exhaustion and the component of professional involvement. At the same time, we observe an increase in the level of burnout during the COVID-19 pandemic (in the study conducted before the pandemic, doctors obtained average scores of 40.66 out of 64 possible), while following the questionnaire applied during the pandemic the average scores were 43 of 64) (Figure 1).

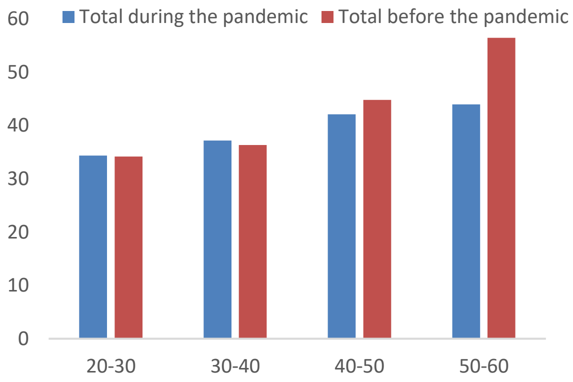
Figure 1: Results obtained broken down by personnel categories



Also, we notice the biggest difference between the two periods among the nurses, before the pandemic the scores obtained were on average 29.43, unlike the current ones, which had an average of 34.57, the difference is due mainly to the marked increase of the exhaustion component. At the opposite pole, with the lowest level of burnout remain the outpatients, although comparing the results obtained in the two questionnaires, we notice among them a sharp increase in burnout.

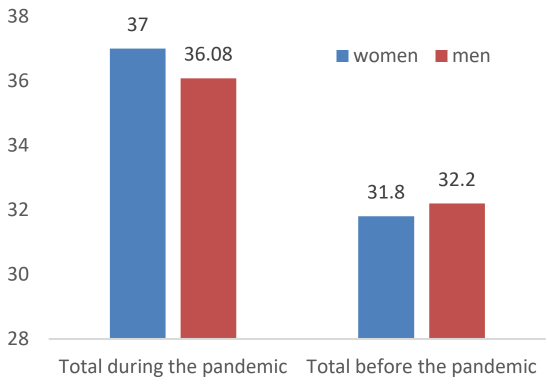
If we talk about age, we observe the increase of the burnout level concerning the advancing age (Figure 2). This can be explained by the accumulation of fatigue due to the extended work schedule and the accumulation of problems at work with those in private life.

Figure 2: Results according to age



A perhaps surprising aspect was the fact that there were no notable differences in the degree of burnout between the men and women interviewed in any of the questionnaires. In the first questionnaire, the average values varied around 32 points, while in the second questionnaire the average values were 36.5 points (Figure 3).

Figure 3: Results according to sex



CONCLUSIONS

In recent years, interest in burnout has increased, being a syndrome more and more common in developing countries and with an increased impact in both personal and professional life.

Healthcare personnel represents one of the most exposed professional categories to this syndrome, due to overtime, desire to treat all patients, fear of failure, inability to suffer from certain pathologies, and exposure to additional factors in the workplace: physical, biological, chemical factors.

The COVID-19 pandemic was an additional stress factor for medical staff, on the one hand, due to the numerous unknowns related to treatment, prevention, disease evolution and on the other hand, due to the intensive work regime in special conditions, being forced to comply to a set of additional rules and the period in which they had to be separated from their loved ones to protect them.

According to the study conducted between May and June 2020, there is an increased level of burnout of health care personnel, the highest score being obtained by doctors.

Comparing the results highlighted by the questionnaire applied before the COVID-19 period with those obtained in the questionnaire applied between May and June 2020, we notice an increase in the level of burnout in all categories interviewed during the pandemic.

There is also a gradual increase in the level of burnout proportional to aging, but slower than before the pandemic.

The percentage of burnout reported by sex groups is close, with no significant differences between men and women. But even in this case, there is an increase in the incidence of burnout in the last 4 months.

Therefore, burnout syndrome remains a common problem in the health field, especially affecting doctors, probably because they represent a complex interface with patients, relatives, the rest of the ER staff, doctors from other specialties; have the responsibility of the performed medical act; working hours over time due to the need for continuous training.

To decrease the incidence of this syndrome, but also its effects, it is important to apply various means of prevention such as identifying and combating the triggering factors, observing and early intervention on the disease, and treating the effects produced by it.

On this basis, we conclude that stress, exhaustion and distress lead to the development of the burnout syndrome, which, in this period is conspicuously increased by the

COVID-19 pandemic, essentially breaking what should be the first and most important rule of any medical practitioner: the safety of the rescuer.

REVIEW

Cannabinoids – a new therapeutic strategy in neurology

Carmen A. Sirbu[1], Aida M. Manole[2], Titus M. Vasile[2], Gabriela S. Toma[3], Livia R. Dobrican[4], Dan G. Vîrvara[4], Octavian Vasiliu[4]

Abstract: *Cannabinoids' usefulness in the treatment of neurological disorders (epilepsy, and various neurodegenerative diseases, such as Multiple Sclerosis and Alzheimer's Disease) has been demonstrated in a growing number of studies. Of the 11 known general types of natural cannabinoids, the focus has been mainly directed at cannabidiol (CBD) due to its specificity in stimulating cannabinoid receptors and the low rate of side effects, as well as on Δ (9)-tetrahydrocannabinol (Δ9-THC). The natural and synthetic analogs of CBD have been described as a potential treatment in neurological diseases, as they showed their therapeutic benefits in reducing the seizures from epilepsy and their neuroprotectivity in neurodegenerative diseases. First and foremost, CBD's neuroprotective properties are due to its capacity to act as an endogenous cannabinoid receptor agonist. Second, CBD enhances neuroprotection by interacting with many signal transduction pathways mediated indirectly through cannabinoid receptors. CBD also reduces the hyperphosphorylation of glycogen synthetase kinase 3 (GSK-3) induced by the buildup of Amyloid β in the physiopathology of Alzheimer's disease.*

Keywords: *cannabinoids, cannabis, endocannabinoid, marijuana, epilepsy, multiple sclerosis, Alzheimer's disease*

INTRODUCTION

Traditional medicine based on phytotherapy uses cannabis to treat various ailments and symptoms, such as arthritis, seizures, pain, nausea, and vomiting [1]. CBD is a phytocannabinoid found in the Cannabis plant, although only in trace amounts in western strains. CBD, unlike Δ9-THC, has neither euphoric nor hallucinatory effects [2]. CBD is also implicated in several pathological processes, including neurotransmitter release control, given that it is already known as a potent anticonvulsant, regulating pain, used primarily in patients with oncological pathologies, adjusting gastrointestinal function, which comes in aid of the side effects caused by the chemotherapy and it also possesses antipsychotic potential.

The Cannabis or Cannabaceae plant has been used in traditional medicine, beginning with the medicine practiced in the East, for about 5000 years as an analgesic, anxiolytic, anticonvulsant, sedative, as well as a hypnoinducer. Botanists used morphological criteria to organize Cannabis into three types: Sativa, Indica, and Ruderalis. The last one is the most studied subspecies, as it is most frequently encountered in Western countries [3]. Recently, pharmacological studies have indicated that the cannabis plant has many properties, such as antiepileptic, anti-parkinsonian effect [4], pain-killer [5], antiseptic [6], anti-inflammatory [7], antihistamines [8], blood pressure regulator and anti-coagulant [9] effects. In clinical settings, cannabis has shown its efficacy in oncological diseases, based on its antitumor impact, and in the therapeutic management of specific neurological disorders [10,11]. Current changes in the legal status of cannabis use allow the study of cannabinoids for treatment purposes in a secure and endorsed medical setting [12].

It is known that the diversity of the effects of cannabinoids is mediated by the activation of the G protein, which fulfills the function of a receptor, to which endogenous ligands called endocannabinoids usually are bound. The endocannabinoid system comprises endogenous fatty acid

ligands for cannabinoid receptors, also known as endocannabinoids, and proteins involved in endocannabinoid biosynthesis and breakdown (ECS).

Cannabinoid receptors type 1 and 2 (CB1 and CB2), which have seven transmembrane domains and are found in various tissues, are this system's central receptors [13]. CB1 receptors are primarily found in the cerebellum, basal ganglia, and limbic system, including the hippocampus [13]. Also, the reproductive systems of both men and women include these receptors. CB2 receptors are mainly present on the cellular membranes of immune cells in the periphery, particularly in peripheral lymphoid organs like the tonsils and spleen [14]. CB2 receptors have been found in the central nervous system (CNS) and have a variety of effects, according to the most recent data [15]. Only two of the five endocannabinoids that bind to CB1 or CB2 are particularly important; they appear to play a role in CNS function, especially 2-AG (2-arachidonyl-glycerol) and AEA (anandamide).

We refer to cannabinoids as a category of natural chemicals found in marijuana plants (the most studied species being Cannabis sativa). Compounds that are physically or pharmacologically similar to (9)-tetrahydrocannabinol are among these chemicals, which bind to cannabinoid receptors [16].

The two main compounds in cannabis are Δ (9)-tetrahydrocannabinol (Δ9-THC) and cannabidiol (CBD). Each of them has exhibited different actions from a pharmacological point of view. The presence of psychotomimetic and addictive effects of the primary psychotropic component (Δ9-THC) has led to apprehension about using cannabis for medicinal purposes. On the other hand, CBD inhibits the absorption and hydrolysis of anandamide (AEA), a key endocannabinoid, while having antagonistic effects on 9-THC [17].

Table 1: The main categories of cannabinoids

1	(-)-Δ9-*trans*-Tetrahydrocannabinol (Δ9-THC) [22]
2	(-)-Δ8- *trans*-Tetrahydrocannabinol (Δ8-THC) [22]
3	Cannabigerol (CBG) [22]
4	Cannabidiol (CBD) [23]
5	Cannabielsoin (CBE) [24]
6	Cannabichromene (CBC) [25]
7	Cannabinodiol (CBND) [26]
8	Cannabicyclol (CBL) [27]
9	Cannabitriol (CBT) [28]
10	Cannabinol (CBN) [25]
11	Various types [18]

Over the last few decades, significant progress has been made in researching the natural compounds contained in the Cannabis plant. At least 120 compounds have been identified as natural cannabinoids, including their derivatives and metabolites [18]. Given their structure, these natural cannabinoids can be classified into 11 categories, as shown in Table 1. Due to their diverse and complex structure and multiple substituents, number 11 in Table 1 includes another 30 subtypes with different skeletal shapes [19–21].

Cannabidiol was first isolated in 1940 by Roger Adams and his team of researchers at the University of Illinois [31]. Its chemical structure was described in 1963 by Mechoulam [29, 30]. In 1977 Jones identified two optical isomers of this compound, (-) - CBD and (+) - CBD, the first form being found naturally in the Cannabis plant, while the latter can only be obtained through organic synthesis [31].

THE USE OF CANNABINOIDS FOR THERAPEUTIC PURPOSES

CBD has been shown to offer neuroprotective advantages in the treatment of multiple sclerosis (MS), epilepsy, Alzheimer's disease (AD), and other pathologies caused by degeneration or abnormal nervous system activity in preclinical and clinical research.

Epilepsy

This disease affects 65 million individuals globally [33] and significantly impacts seizures, mortality, comorbidities, stigma, and associated healthcare costs. Significant progress has been achieved in understanding the pathophysiological underpinnings of the disease and the factors that influence its prognosis over the last decade. New conceptual and operational definitions of epilepsy, as well as altered diagnostic and classification criteria and nomenclature, have all contributed to these advancements.

Even though the number of antiepileptic medications available has expanded dramatically over the last 20 years, about one-third of patients remain drug-resistant. Despite the efficacy of surgical operations, which have resulted in more than half of all operated patients experiencing long-term seizure remission, this treatment method is still reserved for a small subset of drug-resistant patients. The quality of life of most individuals with epilepsy continues to be negatively affected by deficiencies in knowledge regarding the pathogenesis, diagnosis, treatment, education, legislation, and research in this field.

The anticonvulsant effect of cannabidiol has been researched in multiple studies, conducted both in vivo and in vitro. Stimulation of CB1 receptors is followed as the primary target for antiepileptic effects in animal studies.

Neurophysiological studies have confirmed that glutamic acid is the major excitatory neurotransmitter in the CNS. Excessive glutamate release causes neurotoxicity, extreme excitability, and epileptic seizures in mice and primates. The direct result of activation of CB1 receptors is a reduction in glutamate release on a presynaptic level. Decreased glutamate release leads to an anticonvulsant effect and thus constitutes a target within antiepileptic therapy. In addition, endocannabinoids act upon specific ion channels by activating the G-receptor protein complex, which models the intracellular concentration of K+. The effect exerted upon K+ channels may decrease neuronal excitability, thus preventing seizures by stabilizing the membrane potential and reducing other epileptogenic factors [34]. When CB1 receptors in the neuronal body are engaged, the activity of an extracellular kinase, which impacts neural signaling and the synthesis of brain-derived neurotrophic factor (BDNF), has been shown to increase [35]. The latter plays a long-lasting protective role in the hippocampus [35].

CBD acts through endocannabinoids to activate CB1 receptors, stimulating a cascade of phenomena, which play a protective role against toxicity caused by excessive neuronal stimulation. Thus, the information mentioned above suggests that CBD can become an essential therapeutic instrument for neuron diseases, whose trigger mechanism consists of hyperexcitability and neurotoxicity [36].

In addition to acting on CB1 and CB2 receptors, CBD works at low doses on transient receptor potential (TRP) channels, affecting cationic channels and decreasing glutamate release in the presynaptic cleft. TRP is a group of channels that modulate ion entry and mediate various neural signaling processes [36,37]. Moreover, CBD will activate 5A-hydroxytryptophan 1A (5-HT1A) receptors and inhibit adenosine reuptake through multiple mechanisms, so that cannabidiol may have anti-inflammatory and antioxidant effects [37–41].

There is a long history of unofficial use of CBD in epilepsy and other neurological disorders because many preclinical studies have shown favorable neurological effects. Ever since the end of the 19th century, physicians in England and the United States have observed a reduction in the incidence of seizures in patients treated with cannabinoids [42]. Another study indicated that CBD reduced the susceptibility of seizures induced in laboratory mice by accompanying stimuli [43]. CBD is an adequate anticonvulsant with higher selectivity and fewer neurotoxic consequences compared to classical antiepileptics. Also, CBD can shorten the duration and amplitude of the post-critical phase through increased selectivity and reduced excitability acting on the central nervous system. In 2017, the Epilepsy Therapy Screening Program (ETSP) was established by the American National Institute of Neurology and Neurovascular Diseases to investigate the effects of CBD on a variety of epileptic seizure models. CBD has been found to have anti-seizure activities in both humans and mice with epileptic seizures after stimulation by ETSP. [44]. In June 2018, the FDA approved an anti-epileptic drug that contains CBD, named Epidiolex, for treatment-resistant epilepsy (Lennox-Gastaut syndrome and Dravet syndrome) [45].

Multiple sclerosis

Autoreactive T cells invade the CNS, followed by clonal growth, with a preference for myelin or other CNS proteins. Different autoimmune cells, such as microglia and B lymphocytes, are also initiated, and when combined with T cells, they develop into a "cytotoxic" cascade that demyelinates neurons in the brain and spinal cord. The presence of both CB1, as well as CB2 receptors has been noted on the surface of specific cells around the platelets accumulated in the demyelinated areas present in MS [46]. Increased CB1 and CB2 receptors activity were observed in some MS patients' bloodstream in a 2009 study, suggesting that activating the endocannabinoid system, both inside the brain and in the periphery, can restrict inflammatory, immunological responses [47].

In 2007, an elevated level of AEA (anandamide) was identified in conjunction with the number of inflammatory lesions noted in the neurological images [48]. It has been pinpointed that the level of multiple endocannabinoids within the cerebrospinal fluid has a low level in patients with remission, but an increased level in those with active inflammatory lesions, in a study conducted in 2008 [49]. These three studies illustrate a correlation between MS and the regulation of endocannabinoid activity and demonstrate the influence of inflammatory processes and neural activity on the endocannabinoid system.

Nabiximols, in the form of oronasal spray containing Δ9-THC and CBD, is a product licensed in Great Britain and some countries within the European Union to be used as a treatment for MS, and it has been shown to present a therapeutic effect on neuropathic pain and in the case of sleep disorders [50]. As the following studies have shown [51–53], Nabiximols could also be used to control spasticity. In 2007, a study carried out on 189 patients who were administered Nabiximols over six weeks, compared to the placebo group, showed a substantial reduction in spasticity in the active treatment group [51]. A meta-analysis indicated that these cannabinoids exhibit favorable effects for both neuropathies and pain symptoms caused by spasticity [52].

Another retrospective study [53], carried out in eight centers in Belgium, followed 276 patients with MS-specific spasticity who began treatment with Nabiximols-containing oromucosal spray on March 1, 2016, after other conventional treatment regimens for spasticity were exhausted. The conclusion reached was that more than 60% of patients reported a clinically relevant symptomatic improvement and continued treatment over 12 weeks [53].

Endocannabinoids play a role in limiting the cytotoxic processes which occur during the inflammatory cascade, which initiates the neuronal damage in the context of MS via stimulation of the CB2 receptors. Likewise, stimulation of CB1 receptors may also have beneficial effects by inhibiting glutamate release and the depolarization induced by it. The activation of CB2 receptors in T cells and CB1 receptors within neurons is thought to be responsible for 9-THC's neuroprotective action in multiple sclerosis. In addition to their shown capacity to lower inflammation and excitotoxic lesions in MS, cannabinoids may aid in the repair of myelin sheaths in the axons [54].

Multiple studies have shown the effect of cannabis on the modulation of the myelination process in the developing brain by stimulating CB1 and CB2 receptors [55], in the normal adult brain [56], and in the irritated brain in the TMEV (Theiler's murine encephalopathy virus) model of MS [57]. The TMEV model's accelerated myelination process could be related to the efficacy of cannabis in reducing inflammation which detained the remyelination. Alternately, cannabinoids may have an exhilarating response to myelination by improving survival [57] and cellular division of oligodendrocytes [55]. Further study of changes occurring in MS in conjunction with the endocannabinoid system may lead to the development of novel therapeutic methods.

Alzheimer's disease

This chronic neurological disease is currently the leading cause of dementia worldwide, facing an acceleration of diagnostic that will bring us to an epidemic with 150 million cases globally by 2050 [58].

The pathogenesis of the disease is highly correlated with the accumulation of extracellular aggregates of amyloid β (Aβ) plaques and intracellular neurofibrillary tangles of TAU protein located in a different region of the brain, which drives the dissolution of microtubules in neurons, spoiling the architecture of the cytoskeleton of the cell, fracturing the neural transport system and causing a significant loss of neurons firstly in the hippocampus, which clinically leads to memory loss. These actions initially bring some biochemical communication disengagement in the connections between neurons, followed by neuronal death [59–61]. This is our current knowledge of the pathophysiology of AD, but as the mechanism is not fully understood, the therapeutical resources are very limited. Even if it has been shown in some studies on animal models that THC can have a direct effect on amyloid β (Aβ) aggregation, the psychoactive properties limit the possibilities of being used as a medication. Although other non-psychoactive cannabinoids, such as CBD, show neuroprotective activity on animal models by reducing oxidative stress and playing a role in microglial inflammation. Cannabidiol’s effect on inhibiting neuronal apoptosis by regulating pro-caspase-3 levels and decreasing caspase-3 levels has shown that CBD exerts a protective effect on the nervous system [65]. In another study, CBD was successfully used to counterbalance Aβ-induced Ca2+ growth, adequately added to the already known antioxidant effect [66]. Furthermore, cannabinoids can stimulate the clearance of intraneuronal amyloid-β and induce a protective effect on old age-associated nervous cells. In addition, they function in the absence of cannabinoid receptors in some cases. CBD increases cerebral blood flow mainly in the areas involved in memory processing, like the hippocampus [66]. In conclusion, cannabinoid products can be an alternative compound for AD drug therapy, but more longitudinal studies must be conducted.

CONCLUSION

Even though higher usage of cannabis extracts is linked to an increased risk of psychosis, CBD can help with epilepsy convulsions and the symptoms of neurodegenerative diseases like AD and MS because of its neuroprotective effect. If the exciting discoveries related to the cannabinoid-mediated weakening of the inflammatory process, the enhancement of remyelination, and behavioral and symptomatic changes are confirmed, these compounds can be used as a treatment for multiple sclerosis as they progress from studies on animal models model systems to humans trials.

Even though various molecular signaling pathways and targets linked to CBD have been identified and summarized, many questions remain unanswered. Finally, natural analogs of Cannabidiol, as well as metabolites and synthetic derivatives enriched with strong biological effects [68] and low neuronal toxicity should be studied for their potential benefits in the treatment of neurodegenerative illnesses such as AD, multiple sclerosis, and epilepsy.

More research is needed to understand how CBD affects the nervous system's growth factors, neurotransmitters, and electrophysiological activity.

Can peritoneal carcinomatosis of colorectal origin be treated with oral everolimus alone or in combination with capecitabine? Preliminary results

Mehmet E. Yuksel[1], **Osman Yuksel**[2]

Abstract: *Background: We wanted to evaluate the effectiveness of oral everolimus alone and in combination with capecitabine treatment on colorectal cancer-induced peritoneal carcinomatosis animal model.*

Methods: Caco-2 colon adenocarcinoma cells were injected intraperitoneally to BALB/cOlaHsd-Foxn1nu mice to establish peritoneal carcinomatosis. Mice were divided into four groups (everolimus, everolimus plus capecitabine, capecitabine, control group) with 2 mice in each group. Treatment was initiated 5 days after inoculation of Caco-2 cells. 7.5 mg/kg everolimus was administered orally every 2 days. 2.1 mmol/kg capecitabine was administered orally every 5 days a week. 22 days after inoculation of Caco-2 cells, mice were sacrificed.

Results: The mean weight of the tumor was 25 ± 7.07 mg in the control group (n=2); 0.7 ± 0.7 mg in the everolimus group (n=2); 0.28 ± 0.36 mg in the capecitabine group; 0.48 ± 0.07 mg in the everolimus plus capecitabine group.

Conclusion: Tumor samples excised from BALB/cOlaHsd-Foxn1nu mice revealed that everolimus alone, and in combination with capecitabine suppressed tumor growth. However, a comparison of tumor weights revealed no statistically significant difference within the four groups (p=0.227). To reach statistically significant data, the sample size should be increased.

Keywords: *colon cancer, everolimus, peritoneal carcinomatosis*

INTRODUCTION

Peritoneal carcinomatosis secondary to colorectal cancer progression is characterized by the formation of solid tumor deposits on peritoneal surfaces [1]. Even today, chemotherapy protocols plus cytoreductive surgery and hyperthermic intraperitoneal chemotherapy applied for the treatment of metastatic colorectal cancer have been able to increase the median survival up to between 20-62 months at most [2-4]. Moreover, chemotherapy protocols used for the treatment of advanced colorectal cancer contain intravenous (iv) interventions and hours of chemo-therapeutic agent infusions, which reduce both patient compliance and comfort.

In search of novel treatment options for peritoneal carcinomatosis of colorectal origin, an article published by Wagner et al. in 2009 drew our attention, in which they claimed that effective treatment of advanced colorectal cancer by rapamycin and 5-fluorouracil (5-FU)/oxaliplatin was achieved [5]. Rapamycin is both an antibacterial macrolide group antibiotic and a mammalian target of rapamycin (mTOR) inhibitor [6, 7]. Phosphatidylinositol-3-kinase (PI3K)/AKT/mTOR signaling pathway is a central regulator in cell proliferation, cell growth, and angiogenesis [8-10]. Inhibition of mTOR by rapamycin prevents tumor proliferation and growth [7, 11]. Everolimus is the derivative of rapamycin that can be used orally and it has a higher

bioavailability than rapamycin [12, 13]. Moreover, oral capecitabine treatment in metastatic colorectal cancer is equivalent to iv 5-FU plus leucovorin treatment has given the time to progression of the disease and overall survival [14]. Wagner et al. revealed that when oral rapamycin was administered in combination with iv 5-FU, colorectal cancer-induced peritoneal carcinomatosis was suppressed in a mouse model. However, 5-FU can only be used intravenously. Therefore, we thought that the treatment of peritoneal carcinomatosis with chemotherapeutic agents that could be used orally would both facilitate the compliance of the patient with the treatment and increase the patient's comfort. Thus, this study aimed to administer everolimus and/or capecitabine orally to BALB/cOlaHsd-Foxn1nu mice with colon cancer-induced peritoneal carcinomatosis to examine whether tumor regression was achieved.

MATERIALS AND METHODS

Local ethics committee approval was obtained before the study (Approval number: 2013/60).

Cell Lines and Chemical Substances

Caco-2 human epithelial colorectal adenocarcinoma cells were purchased from American Type Culture Collection (ATCC®, Rockville, MD, USA). Dulbecco's Modified Eagle Medium (DMEM), 10% fetal bovine serum (FBS), Dulbecco's Phosphate Buffered Saline (D-PBS), 0.05% trypsin-EDTA, and trypan blue stain 0.4% from Gibco® was purchased. Everolimus (Certican 0.75 mg, Novartis) and capecitabine (Xeloda 500 mg, Roche) were supplied from the market.

Animal Model

Eight BALB/cOlaHsd-Foxn1nu mice, 14-18 week-old female, weighing 14.1-24.2 g were used within this study. BALB/cOlaHsd-Foxn1nu mice were purchased from Harlan (Israel). BALB/cOlaHsd-Foxn1nu mice have housed in individually ventilated cages at 12/12 hours light/dark cycle at 23° C, and mice were fed with Altromin brand 1414 TPF catalog feed.

Preparation of Caco-2 Cell Culture

Caco-2 human epithelial colorectal adenocarcinoma cells were kept and propagated in DMEM medium containing 10% FBS within a 5% CO_2 incubator at 37°C. Cells were trypsinized when the cells completely covered the culture flask base. Afterward, these cells were counted and the viability of the cells was checked. The trypsinization procedure was performed as follows: The medium in the flask was poured out and washed twice with 10 ml D-PBS. 3 ml of 0.05% trypsin-EDTA was added to the cells and the cells were kept in an incubator containing 5% CO_2 at 37°C for 5 minutes. Cells were collected in a 50 ml centrifuge tube with the help of a Pasteur pipette. Cells were centrifuged at a 1200 rate per minute (rpm) for 5 minutes. After centrifugation, the supernatant was discarded. The pellet was mixed with 1 ml medium. To evaluate the viability of Caco-2 cells, 10 µl of the pellet which was mixed with 1 ml medium was taken. In a 1.5 ml Eppendorf tube, 10 µl pellet and 190 µl, trypan blue stain 0.4% (dilution factor 20, 10 µl pellet in 200 µl mixture) were mixed. 10 µl of this mixture (10 µl pellet and 190 µl trypan blue) were taken and placed on Thoma slide. The viability and number of cells on Thoma slide were determined with a 5x magnification light microscope. (There are 64 squares in four different areas on Thoma slide, and cells in each frame were counted). The total number of cells counted was divided by four to find out the mean value. The mean number of cells x 104 x dilution factor x 1 (1 ml of medium mixed with pellet after centrifugation) formula was applied to determine the number of cells in 1 µl.

Intraperitoneal injection of Caco-2 cells

1,500,000 Caco-2 human epithelial colorectal adenocarcinoma cells were injected intraperitoneally into each BALB/cOlaHsd-Foxn1nu mouse.

Treatment Protocol

Mice were randomly divided into 4 groups (everolimus, everolimus + capecitabine, capecitabine, control group). There were two mice in each group. The mice were taken to laboratory conditions one week before the experiment.

Treatment was started 5 days after intraperitoneal injection of Caco-2 cells into mice. Everolimus was diluted with saline (0.9% NaCl) and administered to two mice orally by gavage every two days at a dose of 7.5 mg/kg [15]. Capecitabine was diluted with saline and the maximum tolerated dose of capecitabine was administered to 2 mice 5/7 days per week by oral gavage at a dose of 2.1 mmol/kg/day (1 mmol capecitabine is 359 mg) [16]. Only PBS was given to 2 mice in the control group by gavage (Table 1).

Mice were daily evaluated. 22 days after the injection of Caco-2 cells into the intraperitoneal cavity, 17 days after starting treatment, all mice were anesthetized with intraperitoneal 50 mg/kg ketamine HCl and 5 mg/kg xylazine, and the mice were sacrificed by cervical dislocation method.

Surgical Procedure

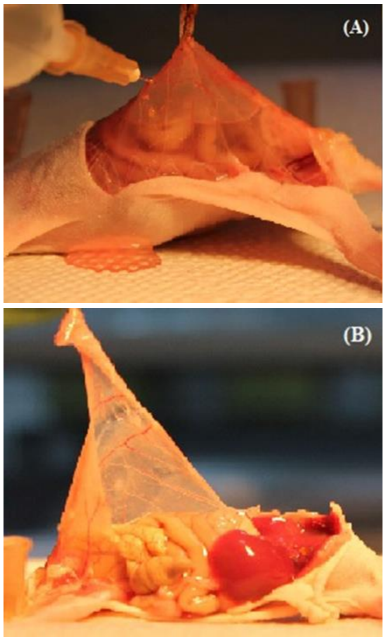
Abdominal skin was opened by protecting the peritoneum with a midline incision. Saline solution was injected into the intraabdominal cavity and aspirated. Intraabdominal peritoneal washing fluid samples were reserved for cytological examination (Figure 1). Afterward, the peritoneum was excised without damaging other organs and the tumor developed at the intraperitoneal injection site was excised. The dimensions of the total tumor tissue removed were measured and the tumor was weighed. Tumor tissue formed in the peritoneum, mesenteric lymph nodes, liver, spleen, kidney, small intestine, colon, stomach, and intraperitoneal injection site were placed in formaldehyde solution for pathological examination.

Table 1: Treatment protocol

	Everolimus	Everolimus + Capecitabine	Capecitabine	Control Group
Number of Mice	2	2	2	2
Dose	7.5 mg/kg	7.5 mg/kg + 2.1 mmol/kg/day	2.1 mmol/kg/day	PBS*

**PBS: Phosphate-buffered saline*

Figure 1: (A) 0.9% NaCl was given into the abdominal cavity intraperitoneally and aspirated. Cytological examination of the aspirated fluid was investigated for malignant cells. (B) Excision of the peritoneum.



Statistical Analysis

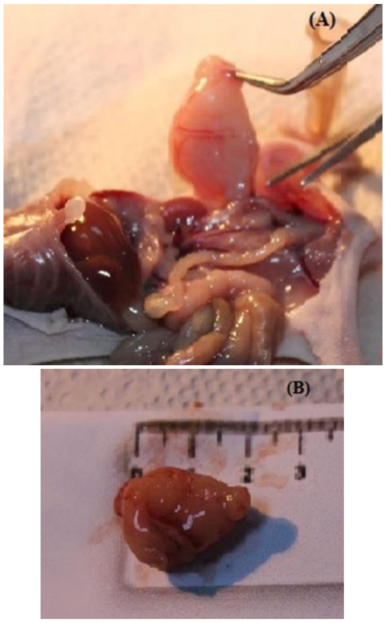
Statistical analysis was performed using SPSS version 15.0. Kruskal-Wallis analysis of variance was used to evaluate the differences between continuous variables. P<0.05 was considered statistically significant.

RESULTS

Control Group

In the first mouse within the control group, a 1.5 cm lesion was observed where Caco-2 cells were injected in the left lower quadrant of the abdomen. The tumor which was located intraperitoneally was excised. The tumor size was 2x1.5x1.5 cm weighing 20 mg (Figure 2). No macroscopic tumor was found in other intraabdominal organs. Poorly differentiated adenocarcinoma was detected in the pathological examination of the tumoral lesion excised from BALB/cOlaHsd-Foxn1nu mouse.

Figure 2: (A) Tumor in the left lower quadrant of the BALB/cOlaHsd-Foxn1nu mouse within the control group. (B) The excised intraperitoneal tumor was 2x1.5x1.5 cm.



In the second mouse within the control group, the size of the lesion was 2.5x1.8x1.5 cm weighing 30 mg. The pathological examination of the excised tumor revealed poorly differentiated adenocarcinoma. No tumor, metastasis, or infiltration was detected in the peritoneum, mesenteric lymph nodes, liver, spleen, kidney, small intestine, colon, and stomach. No tumor cell was detected in the cytological examination of the peritoneal washing fluid.

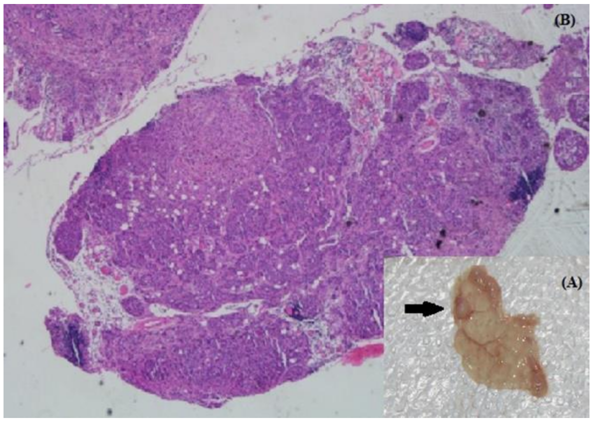
Everolimus Group

During exploration, a tumoral lesion 0.2x0.4x0.4 cm in size, weighing 0.2 mg was detected in the first mouse. The cytological examination of intraabdominal fluid revealed no tumor cells. Tumor size was 1x0.6x0.4 cm weighing 1.2 mg in the second mouse. In addition, metastatic mesenteric, peripancreatic, and perisplenic lymph nodes were detected in the pathological examination. At the same time, two tumor deposits were detected on the small intestine surface. However, no tumor cell was detected in the cytological examination of the peritoneal washing fluid.

Capecitabine Group

In the first mouse given capecitabine, the tumor was associated with peritoneal tissue in exploration. Tumor size was 0.2x0.1x0.3 cm (Figure 3). No other macroscopic tumor tissue was detected. In the second mouse treated with capecitabine, a tumor 0.4x0.5x0.6 cm in size was detected. Apart from the other mice, poorly differentiated adenocarcinoma infiltrating diaphragm striated muscle was detected.

Figure 3: (A) Tumoral lesion detected on the peritoneum. (B) Poorly differentiated adenocarcinoma metastasis within the mesenteric lymph node (Hematoxylin&eosin; x40 magnification).



Everolimus plus Capecitabine Group

Tumor size was 1.2x1x0.8 cm in the first mouse which was treated with both everolimus and capecitabine. However, pathological examination revealed poorly differentiated adenocarcinoma metastases in mesenteric lymph nodes. Tumor size within the second mouse was 0.5x0.6x0.4 cm (Figure 4). No malignant cells were detected in other intraabdominal organs, peritoneum, and peritoneal lavage fluid.

Comparison of Tumor Weights

In the control group, tumor weights were 20 mg and 30 mg. In the group treated with everolimus tumor weights were 0.2 mg and 1.2 mg. Within the group treated with capecitabine, tumor weights were 0.03 mg and 0.54 mg. The tumor weights were 0.43 mg and 0.54 mg within the group treated with both everolimus and capecitabine (Figure 5).

Figure 4: (A) Significant tumor growth was not observed in the localization, where Caco-2 cells were injected. (B) Tumor size was 0.5x0.6x0.4 cm.

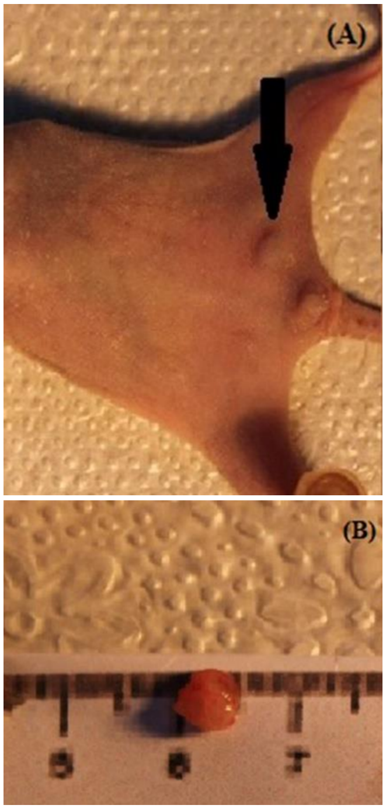


Figure 5: Weights of tumor samples excised from BALB/cOlaHsd-Foxn1nu mice. In mice treated with everolimus and/or capecitabine, tumor growth was suppressed compared to the control group. However, there was not a statistically significant difference between the four groups (p=0.227)

DISCUSSION

The mTOR (mammalian target of rapamycin) is a serine/threonine-protein kinase [17]. There are two mTOR complexes, mTORC1 and mTORC2 [18, 19]. mTORC1 includes mTOR, Raptor (regulatory-associated protein of mTOR), and mLST8. mTORC2 contains mTOR, Rictor (rapamycin-insensitive companion of mTOR), mLST8, and mSIN1 (mammalian stress-activated protein kinase interacting protein). The mTORC1 eukaryotic translation initiation factor controls protein synthesis through the ED (eIF4E) binding protein (4E-BP1) and p70S6 ribosomal kinase (S6K) [20]. mTORC2 is involved in cell growth. Rapamycin combines with FK506 binding protein (FKBP) 12 to block mTOR activity. The mTORC1 is sensitive to rapamycin, while mTORC2 becomes susceptible to rapamycin only if it is exposed to the rapamycin effect for a long time [21]. Rapamycin-like drugs such as everolimus, temsirolimus, and ridaforolimus which are called rapalogs, have been produced after the anti-tumoral properties of rapamycin were discovered [22].

Nowadays, everolimus is used because of its tumor suppression feature in patients with subependymal large cell astrocytoma, advanced breast cancer, progressive pancreatic neuroendocrine tumor, subependymal giant cell astrocytoma, and advanced renal cell carcinoma [22]. In addition, capecitabine is used for the treatment of colorectal cancer and metastatic breast cancer [12, 23-25]. The side effects of both everolimus and capecitabine are very well known in detail because they are included within the current treatment protocols [26-28].

The positive effect of everolimus on peritoneal carcinomatosis has been demonstrated in several experimental models. Taguchi et al. used 58As1 human stomach cancer cell series, which were prone to peritoneal metastasis, to demonstrate the effectiveness of everolimus in advanced gastric cancers with peritoneal spread, and showed that everolimus significantly reduced peritoneal spread [29]. Chu et al. tested everolimus on a human colorectal carcinoma cell line with KRAS mutation in a mouse model and revealed that everolimus alone had significant antitumor activity [30]. Mabuchi et al. reported that everolimus delayed tumor onset and progression in the transgenic mouse model in ovarian cancer [31]. Moreover, studies on humans investigated the effects of everolimus on tumor growth when used as a single agent. Okamoto et al. published the results of phase 1 studies on daily everolimus treatment for patients with advanced solid tumors and reported significant tumor shrinkage in patients with esophageal and gastric cancer with 10 mg/day everolimus treatment [32]. However, Yoon et al. stated that 10 mg/day of everolimus treatment had only a limited impact on advanced gastric cancer [33]. There have been also phase studies on human beings with everolimus and capecitabine. Deenen et al. published the results of the phase I study of oral capecitabine and everolimus treatment in patients with advanced solid cancers [34]. In this study, 18 patients with the primary pancreas, major duodenal papilla, esophageal, gallbladder, brain, osteosarcoma, and hepatocellular cancer were treated with capecitabine 1.000 mg/m^2 bid and everolimus 10 mg/day every 3 weeks for 14 days, and prolonged clinical efficacy was observed in 39% of patients with advanced solid malignancies. Lim et al. published the results of a phase I study of capecitabine and everolimus treatment for patients with previously treated metastatic gastric cancer [35]. Fifteen patients with metastatic stomach cancer who had progression after chemotherapy were included in the study. With 650 mg/m^2 capecitabine twice daily and 5 mg everolimus twice daily, the median time without progression of the disease was 1.8 months (range: 0.8–2.8 months). At the same time, the reduction in the longest diameter of the tumor was 28.7%.

In our study, tumors formed in mice within the control group were approximately x20 times larger than tumors excised from other groups, however, tumor growth in the control group was limited only to the inoculation site of Caco-2 cells. Everolimus and capecitabine treatment suppressed primary tumor growth in the region where Caco-2 adenocarcinoma cells were injected. No liver toxicity or mortality were observed during treatment with everolimus and/or capecitabine.

In light of these findings, the mTOR inhibitor everolimus suppressed tumor growth in the mouse model of colon cancer-induced peritoneal carcinomatosis when administered orally or in combination with capecitabine. However, the limitation of this study was the small sample size. Our study is unique because it has investigated whether peritoneal carcinomatosis could be treated with oral chemotherapeutic agents. However, to reach a definitive conclusion, it is necessary to work with a larger experimental group.

Acknowledgments

I would like to thank Prof. Emin Umit Bagriacik, Assoc. Prof. Ozgur Ekinci, Dr. Emine Avci, Serhat Ozgermen, and Basak Ozgermen for their valuable contribution.

This study was presented at 49. Congress of the European Society for Surgical Research as an oral presentation on 21-24th May 2014, Budapest, Hungary.

VARIA

Can we still manage the relationship with patients?

Liana Manolache[1]

Eighteen years ago, I started my out-patients' experience as specialist dermatologist. I worked from the very first day with National Health Insurance System. It was a chance to build a huge experience (more than 120,000 visits since then). Over time, relationships with patients have changed, influenced by many factors. To preserve good relationships we have to reflect and to use different approaches.

In 2001, my stamp and my signature were enough for a consultation. The cell phone era was at the beginning. Over the years, the process has become more and more complicated. Today, if the computer, internet, different types of applications, software, other devices (printer, card reader, etc.) are not working, my knowledge becomes absolutely necessary, but not sufficient for a consultation. So, the doctor is now, totally dependent on IT issues. Besides instant information, cell phones induce a lack of intimacy. Everyone could reach you everywhere, every moment. You are almost "forced" to give advice on whatsapp, e-mail, messenger and people expect you to answer on-site, otherwise you are not "reachable".

Time is the first pressure that we are feeling. Patients want and expect a consultation as soon as possible even you have appointments for the next few weeks. I try my best not to push later than 10 days, if it is a new ordinary consultation. Sometimes, it is possible for me to see the patient on-site (a child, an emergency, pregnant women, etc.). In the literature, time for appointment could vary from 7 working days in Brazil [1], to median 41 days in Canada (Ontario) [2] or median 45 days in US (Pennsylvania) [3] to a certain dramatic situation waiting list of 57 weeks in a unit in UK [4]. The number of consultations tends to increase. It is not only a perception, but a reality, revealed also by a French study (21% increase from 2000 to 2010) [5].

Time is also a burden for the doctor, because the real time for consultation has dramatically reduced in favor of bureaucratic issues. Official papers seem to be more important than people. It is a constant effort to remain emphatic and to really listen to patient's history. The stories that we are ignoring for lacking time could give us important clues for diagnosis, approach, could enforce the relationship and give trust, could relief the worries.

"You are the 5th dermatologist I am seeing"- a young woman told me the other day. I looked at her: she was around 20, some pimples on her jaw (not too many) and some tiny scars on her forehead covered by a lot of makeup. Not quite a good start for a relationship. Her expectations were not fulfilled by visiting the other doctors. Maybe the expectations were not realistic, maybe she was fed up trying different things. "How can I propose something new or miraculous when she tried probably "everything"? - I asked myself. I spent at least half an hour discussing about acne, therapeutic options and adjusting the expectations to our limits. It was more a counseling session than a dermatologic consultation.

Today, patients are coming in our office very informed. They "know" the diagnosis and sometimes even the treatment they want or need. After "Dr. Google" you can be a second opinion. Dermatology is underestimated even by other physicians that feel competent enough to prescribe medication inducing iatrogenesis [6]. So, what to expect from patients? It is a good thing to have an informed patient. It will save you a lot of time and energy in expanded explanations. But, there is also a lot of incorrect or

---

[1] Dali Medical, Bucharest, Romania

misunderstood information, prejudices from other's experience shared on forums, incorrect auto-diagnosis or even incorrect auto-medication. It is our duty to listen and to correct, as much as we can. Patients have to be taught how to choose important information from the constant "soup of news feed".

The flux of information is huge, also for doctors as for patients. Thousands of opinions, articles, and new approaches invade our space daily. A good selection criteria for useful, relevant data is absolutely necessary.

A "happy" patient seems to be the one with a certain diagnosis, with clear treatment plan, including explaining side effects and with a contact number in case of recurrence [7]. The access of any information being so instant, patients expect a rapid response of the treatment. The result has to be now and definitive. The pressure of quick response is not very subtle, the doctor feeling it as a burden. It takes time to explain and to understand the progression of chronic illnesses.

Sometimes, the expectations are to get well with any treatment, eventually without any changes of their life style, even when doctor explains that some habits could aggravate or maintain the lesions. Taking responsibility for some adjustments is an important part to discuss with patient, as part of therapeutic approach. Paternal, omniscient doctor's image is no longer in actuality and patient is an important part of the relationship. Instead of an "infantile" patient, coming for any transitory rash or any mosquito bite, it is better to "grow" him/her as a self-confident "partner". The new and healthy bond has to transform patient from the passive, sometimes passive-aggressive role, into an assumed, informed, pro-active one. Cooperation is the key of healthy relation. Patient has the right to ask for explanations, to discuss therapeutic options, to refuse treatments. Patients have opinions that have to be respected and sometimes corrected if they are distorted. On the way to get therapeutic alliance and long-term cooperation, the doctor-patient relationship has to be personalized, giving value to it. This kind of relationship will make the difference in the end and even the direction is to involve more high tech and robots. Face-to-face relationship will not be replaced by anything and it will be highly appreciated after the "speed" condition passes. More social skills are often required, doctors not being known as the best communicators. Sometimes, doctors are not aware of patients' perception regarding communication [8]. I have got my social skills working day by day, no special courses were made during faculty, unfortunately. "We need fewer memorizers and more thinkers and communicators in modern medicine" is the most recent conclusion of Canadian Debate Series regarding medical students' selection [9].

Another pressure point is the constant fear of errors. With all the efforts of protocols for reducing the risk of mistakes or misconducts, unfortunately there are lots of gaps and debates. The fear of error and malpraxis leads to excess of medication and investigations, sometimes too expensive and useless.

Doctors should not be scared by the abundance of products, instruments, techniques, aggressively promoted. They have to be more flexible, more intuitive and more eager to try, making personal experience and not taking results for granted. Many of these products will not pass the test of time, even they are presented as "miraculous". Sometimes, patients' needs are the trigger for experimenting new methods and push us to progress faster.

Not only patients are in a rush, doctors too. The race for EMC points is making the doctor more informed, but we have to be careful not to become too superficial. Even a doctor is getting a diploma after a "3 days course", it doesn't mean that he/she will be an expert in that field, not even competent. It will take a lot of time and energy to really get the expertise, that course being only the very first step on the road. The "diplomas wall", real or virtual is a false goal. In the end, the real skills are more important than a sublime image and it will take time to get them.

Sometimes, vanity makes the teamwork harder. This will be unproductive for both doctors and patients. It is not a shame to refer the patient to an expert on a field when you feel that you have reached a limit.

People are hardly trying to change our state from patient to client, that new status being debatable. Being a client means to take some responsibilities as in a contract. That is the good part. But, fortunately, remaining a doctor means more than providing services. Practicing medicine is a state of knowledge, art, experience, intuition, with magic touches sometimes.

Fortunately, with all the changes during the last years, dermatologists seem to remain satisfied with their specialty. A recent Mexican study shows that 93% of dermatologists (with an average of 16 years of practice) were happy with their professional life, more than 98% choosing it once again [10].

Maintaining certain levels of professional and personal happiness, keeping informed and open-minded, avoiding burn-out, trying to fulfill patients' expectations, doctors are not in a battle, but in strong alliance with patients.

Cecostomy vs ileostomy for protection of anastomoses in colorectal surgery

Dan Bratu[1], Alin Mihețiu[1], Radu Chicea[2], Alexandru Sabău[1]

Abstract: *Background: The most frequently encountered complication of anastomotic surgery is fistula. In addition to the medical history of the patient, local conditions, the operative moment and surgical technique that were chosen, a series of some other factors can interfere, leading to suture disunity.*

Aim: The aim of the study was to analyze the existence of a relationship between the use of cecostomy (as a mechanism of temporary diversion) and the frequency of anastomotic fistulas.

Materials and methods: We conducted a retrospective study, over a period of 7 years, between 2011-2018 taking into consideration 194 patients who benefited from resections completed with anastomoses in the transverse colon, descending colon, sigmoid and rectum. They were divided into two categories: patients who benefited from cecostomy and patients for whom we did not use this technique. The frequency of fistulas was analyzed for the two main groups and in association with each type of surgery.

Results: It was observed the existence of a relationship between the appearance of fistulas and the use of a decompression mechanism such as cecostomy in the sense of a lower number of fistulas for the first situation (2.66%) compared to 11.76% for cases without cecostomy (p=0.034). The duration of hospitalization in the group with cecostomy was shorter than in those without this derivative stoma and the postoperative recovery was good.

Conclusions: Cecostomy is a useful protection for the anastomosis line, with the advantage that, when the tube is suppressed, the stoma will spontaneously close.

Keywords: *colon and colorectal anastomosis, intraluminal pressure, fistula, cecostomy*

INTRODUCTION

Colon and rectal surgery have encountered multiple complications over time, the most severe and frequent being the fistula. First fistula records come from antiquity (Old Testament and Hindu texts) and Middle Age with enterocutaneous fistulas being described after abdominal injuries. With the occurrence of anastomotic surgery, the first post-anastomotic fistulas were also described, with the initial frequency and mortality being at high levels. Risk of colonic anastomotic fistula continues to range between 1.5% and 23%, with low colorectal and coloanal anastomoses posing the highest risk [1].

Due to the need for achieving mechanical protection of the suture line, various ways of decompressing the perianastomotic colon were imagined. Colostomy, ileostomy and cecal stoma are thus used. These methods, however, have been associated with complications specific to the stomas in general, and often they remain in use for a long time. Anesthetic and surgical associated risk should also be considered, especially in elderly, due to the aged related frailty [2]. It is therefore necessary to find an anastomotic protection method that is effective, with as few as possible of the stoma-specific complications and which can be easily abolished, preferably without surgical reintervention.

MATERIALS AND METHODS

A retrospective study, over a 7-year period extending from January 2011 to December 2018, was conducted at Second Surgical Department at the County Clinical Emergency

Hospital of Sibiu. The data of patients with this type of cancer were obtained from the electronic database, clinical files and operating registers. The aim of the study was to analyze the existence of a relationship between the use of cecostomy (as a mechanism of temporary diversion) and the frequency of anastomotic fistulas.

194 patients were included in the study, patients suffering from cancer located on transverse colon, splenic flexure, descending colon, sigmoid and rectum, on which various types of resections and anastomoses were used.

Data analysis was classified by age, gender, body mass index (BMI), ASA score, tumor location, type of resection and anastomosis, the presence or absence of cecostomy, frequency of fistulas, duration of surgery, and average time of hospitalization.

All the patients were positively diagnosed using colonoscopy, colonoscopic biopsy and computed tomography. There was no neoadjuvant treatment prior to surgery. Comorbidity factors included diabetes mellitus, cardiac pathology, obstructive pulmonary disease, chronic renal failure, liver cirrhosis, hypoproteinemia, anemia. Postoperative complications were followed according to the Dindo Clavien classification. The statistical data and analysis was organized and conducted using the Microsoft Excel Office 365 software. The differences were considered significant if p <0.05.

Surgical technique

After the anastomosis has been completed, the cecum is mobilized, released from adhesion (if any), a Pezzer tube with a caliber between 16 and 24 Fr is prepared and a purse string suture is applied on the anterior surface of cecum (Figure 1). In principle, the place of cecostomy should correspond to the appendicular stump, a maneuver that would keep the patient away from appendicular inflammatory complications. However, even if this was not done, we did not encounter local complications in our study. The cecum is pierced with the scalpel and the tube is inserted into the colon. The suture is tightened and knotted around the Pezzer tube (Figure 2).

A breach is made in the right iliac fossa through which the Pezzer tube is exteriorized. The cecum is fixed to the peritoneum and the probe to the skin (Figure 3). All cases were completed with peritoneal and perianastomotic drainage. In all cases we preferred a post-anastomotic decompression like manual anal dilatation or sphincterotomy. Intraluminal tube was not used (Figures 4-6).

Figure 1: Surgical intervention in relation with leakage site

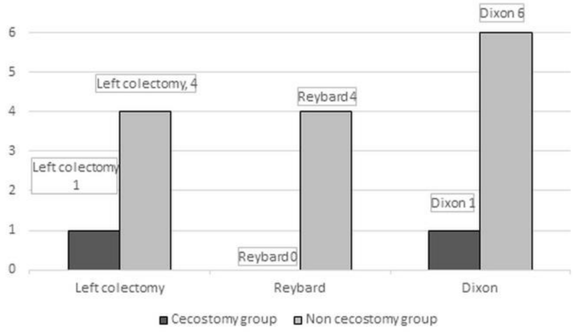

Figure 2: Anastomotic leak complication in Clavien-Dindo classification

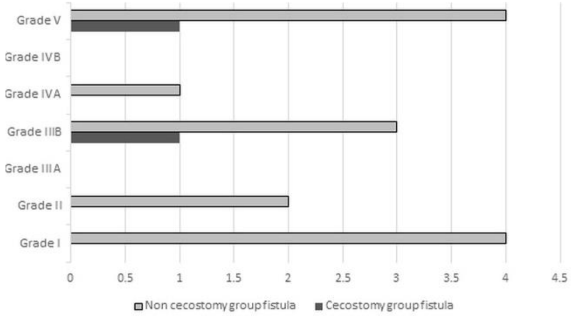

Figure 3: Fistula incidence in our study and in overall literature

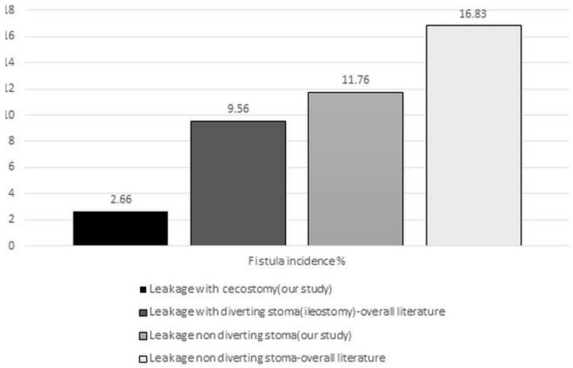

RESULTS

The distribution of cancer on studied colon segments was as follow: transverse colon (9.27%), splenic flexure (11.34%) descending colon (22.16%), sigmoid (39.69%) and rectum (17.52%). Gender distribution in general was 47.93% male and 54.06% women. For the cecostomy group, the distribution was 61.33% in women and 38.66% in male (Table 1).

Of the total number of patients, 75 patients (38.65%) had cecostomy, 119 patients (61.34%) were with no diverting stoma. In cecostomy group cancer repartition was 8% transverse colon, 9.33% splenic flexure, 16% descendent colon, 49.33% sigmoid and 17.33% rectal. Also 28% cases in the first group and 32.77% cases in the second one were anastomosis performed after a previous resection completed with stoma.

Table 1: Characteristics of the patients in the study group

	Cecostomy group	Non cecostomy group
Age (years) median range	62 (38-86)	64.5 (44-85)
Gender female/male	35/40	61/58
BMI kg/m²	27.75 (18.3-37.2)	28 (18.6-37.4)
ASA score (%)		
I	16%	22.68%
II	54.66%	59.66%
III	29.33%	17.64%
Tumor placement		
Transverse colon	6	10
Splenic flexure	7	12
Descendent colon	12	24
Sigmoid	37	48
Rectum	13	25
Blood transfusion	21	39

For the first group surgical techniques applied were segmental transverse colon resection (4%), left colectomy (25.33%), Reybard operation (46.66%) and Dixon operation (24.01%). The statistical analysis obtained was p = 0.042. In the second group the percentage for segmental transverse colon resection was 4.20%, 22.68% for left colectomy, 47.05% in Reybard operation and 26.07% for Dixon technique (p = 0.03).

All cases were resolved by laparotomy, the anastomoses being hand sewn. The average duration of surgery for the group in which cecostomy was used was 146 minutes and 133 minutes for the second group. Three hemorrhagic intraoperative complications were registered being identified and solved. In all cases, hand sewn anastomosis was performed with separate threads in one layer. The most common types of anastomoses for cecostomy group were end to end 77.33%, side to side 13.33% and end to side (9.33%), with a p value of 0.026. Repartition for the other group was end to end 50.42%, side to side 29.41%, and end to side 20.17% (p = 0.011).

The frequency of the fistula in the cecostomy group was 2.66%, with two cases, one with left colectomy status for splenic flexure cancer and the other one with Dixon low rectal resection.

Figure 4: Purse string suture applied on the anterior cecal wall

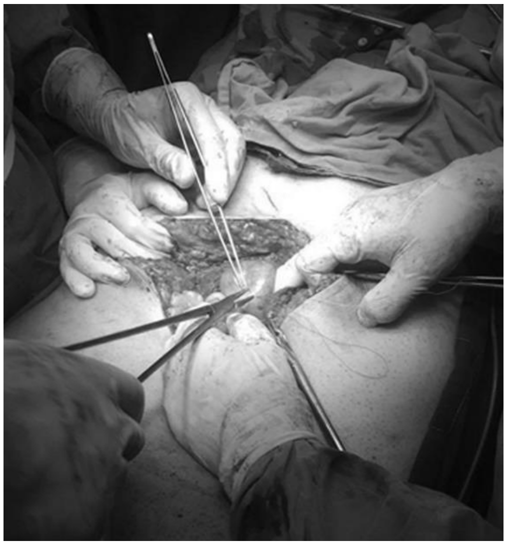

Figure 5: Cecum pierced and prepared for tube insertion

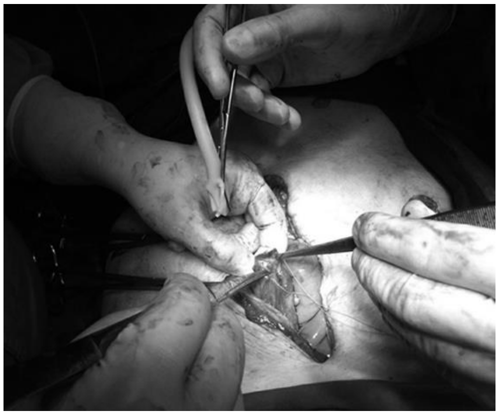

Figure 6: Cecum is fixed to the peritoneum

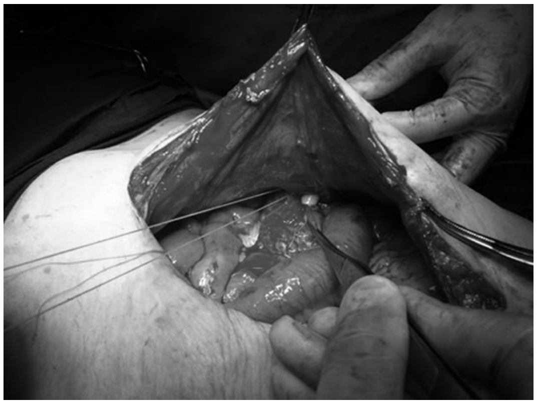

The first case was conservatively treated, the second one was surgically managed by practicing a stoma upstream of the dehiscence. Of the 14 cases with the fistula in the second group, 11 cases were resolved by conservative treatment, in 3 cases surgical approach was preferred, recording 4 deaths.

A statistically significant value p=0.034 was obtained, taking into account the standard value p <0.05. The duration of surgical technique for cecostomy alone was not significantly or statistically increased, the average duration being between 11 min and 5 min with an average of 7.2 minutes. Average length of hospital stay for the cecostomy group was 9.8 days by comparison with 10.3 days in the other group. In the group of patients who presented anastomotic fistula, with cecostomy previously performed the average period of hospitalization was 27.5 days, for the non-cecostomy group being 25.66 days.

The Pezzer tube was removed on average after 8.6 days. No local complications were encountered. The maximum duration of cecostomy drainage was of 14 days after extraction of the Pezzer tube, closing surgery procedures being unnecessary.

DISCUSSION

Colorectal anastomotic leak rates vary from 1.5 to 23% depending on numerous of risk factors such as malnutrition (due to the negative effect in fibroblast proliferation or collagen synthesis) and serum albumin level less than 3.5 mg/dl [1]. Immunosuppression, especially in patients with inflammatory bowel disease on the background of corticosteroid therapy for the underlying pathology and nonsteroidal anti-inflammatory drugs are also known to interfere with anastomotic consolidation [3-5]. Body mass index higher than 25 is associated with a higher risk of fistula.

Fat tissue, diabetes due to chronic complications, low blood levels of hemoglobin (ineffective tissue perfusion) and an ASA score higher than 3 is commonly met along with an increased risk for fistula [6-8]. Mechanical bowel preparation, a controversial topic, with studies that support the usefulness of this maneuver and studies that contradict it. We consider such a maneuver to be useful, it makes a reduction in septicity of the colon. Our experience recommends it to an unprepared colon mentioning that the intervention does not take place immediately after the mechanical preparation of the colon due to edema observed in the colorectal walls after a recent washout [9].

Suture line placement may be the most important factor in the occurrence of a fistula observing that the lower the anastomosis is located, the higher is the risk for leakage [10], many studies link a larger tumor size to a higher risk of fistula [7, 11]. The surgical technique differs according to the surgeon's experience and intraoperative conditions, but the following principles must be respected: achieving a tension free anastomosis and maintaining an effective perfusion on an unobstructed colon [10].

Surgical options include a handsewn or stapled anastomosis in various types, side-to-side, end-to-end, side-to-end, or end-to-side. Additional options include suture material, staple heights, number of layers. It has been demonstrated that regardless of whether the anastomosis has one or two layers, this does not affect the incidence of anastomotic leak, as long as the serosa is apposed and submucosa is incorporated [8]. Beside this particularities, intraluminal postoperative pressure has also its key role in the occurrence of anastomotic breaches.

Thus, postoperatively, the intra-abdominal pressure and the intraluminal pressure increase (by 10-15 mmHg for intraluminal pressure) especially because of paresis of the digestive tract during the period immediately following surgery. Frequently, the moment the fistula occurs corresponds to 5-8 days after surgery, at which time the swelling of the anastomosis is at maximum level, and the intraluminal pressure is at a high level, corresponding to the period in which the intestinal transit is not yet resumed.

Edema of the suture line may predispose to dehiscence, intraluminal pressure intervenes as a decisive factor in causing a further strain on an area of weak resistance with consequent production of leak [12-16].

To prevent pressure effects in the anastomotic area it has been argued that a diverting stoma is an effective and safe procedure to prevent anastomosis leakage complications after colorectal surgery, being imagined different ways of achieving a type of decompression through a diverting stoma such as loop or end ileostomy, colon stoma, cecal stoma, appendicostomy (using vermiform appendix as diverting stoma) or cecostomy [17]. Postanastomotic decompression using manual anal dilatation, sphincterotomy and intraluminal tube used alone are sometimes insufficient. Fistula rates when these procedures are used varies between 5-6% [12, 16, 18]. Intraluminal tube has the disadvantage that it can be mounted only in low colorectal resections. Manual anal dilatation or sfincterotomy are considered useful and had been used in all cases of the study.

The most widely used diverting stoma is ileostomy, more often the loop ileostomy type. Some studies have demonstrated a reduction in the fistula rate in those with ileostomy at values ranging from 3% to 10.9% [10, 11]. On a number of 41 prospective, retrospective and randomized control trials, between 2000-2017, researches that studied anastomotic leakage in patients with colon and colorectal anastomosis for stoma diverting group, the percentage of fistula was 9.56 % and for the non-diverting stoma group was 15.83% [16-22].

The benefits of this method have to be balanced with the specific complications of each type of stoma. The most common complications described were ileus, adhesion syndromes, wound infection and incisional hernias. Mortality associated with anastomotic leakage is raging between 2,1% to 22%. In addition to these, it must be recognized that this type of diverting stoma requires the patient to undergo two surgeries [13, 23-29].

Thus, cecostomy becomes superior to other ways of decompression. Intermittently used in surgery, it comes back in actuality based on an increasingly frequent intention to choose an anastomotic surgery instead of one ended through stoma. Technically it is easy to perform, does not require excessive extension of surgery time, it becomes functional quickly, reducing relating suture-pressure issues (especially the gas pressure) and during its use does not cause difficulty in handling, behaving like a drainage tube. It is recommended to maintain the Pezzer tube for 8-10 days, during which the adhesions process is complete, with the formation of adhesions between the cecum and the parietal peritoneum, the insulation of cecostomy from the abdominal cavity being meanwhile achieved. Suppression of the Pezzer probe does not require any special technique, a simple traction being enough. The area where the cecostomy is placed is covered with a colostomy bag, becoming progressively unproductive - at this time, the cecostomy is closed with a simple bandage on the area. Maintaining a good nutritional support and the use of probiotics improves the patients' quality of life [30, 31].

The advantages of cecostomy are that it is easy to perform, realizes a partial diversion, in transit it is easy to handle and cared by the patient, removal is done without the need for another surgical procedure, and local drainage stops spontaneously after a short time. Temporary diversion ileostomy, compared to cecostomy, implies in our opinion additional statements borne by both the patient and the medical system. In addition to the difficulties of management and care of an ileal stoma compared to a cecostomy, the risk of dysfunctionalities and stenosis of the anastomosis must be taken into account. Also, there is still no consensus regarding the time of instituting oncological treatment in relation to the abolition of ileostomy, the patient may be put in a position to delay chemotherapy. Possible absorption deficits in an ileostomy may increase during chemotherapy, leading to decreased compliance to therapy and increased duration of recovery, or may even affect the outcome of therapy.

The surgical gesture, as well as the anesthesia, especially the general anesthesia in the case of abdominal or pelvic surgery, is an aggression for the body [32]. It is the double exposure of the patient to the risks associated with surgical procedures and immunosuppression associated with additional surgery and anesthesia that we find inappropriate when it comes to two serial interventions. Those risks may be lowered if a minimally invasive, temporary option which does not interfere with cancer treatment and does not require reintervention, is considered [33].

CONCLUSION

We consider mini-invasiveness to be a must in the surgical approach whenever possible. Ileostoma has an additional disabling character, especially for a certain type of patients: the elderly, patients with neuro degenerative or neuro-mental disorders. In addition to all these elements, the cost of stoma care, stoma bags, a new hospitalization, the cost of anesthesia-surgery or postoperative care in the event of complications must be taken into account.

Although out of frequent surgical use, we believe that cecostomy has its advantages over other methods of diversion, and we believe that the tactical option and surgical technique should not be in line with a trend but should be strictly dictated by what brings the most benefits to the patient. The previously mentioned as well as personal experience make us recommend cecostomy as a protection mechanism in colorectal anastomotic surgery because of its safety, spontaneous reversibility and minimal invasivity.

Cecostomy is a safe and effective alternative for diverting stoma in colon and colorectal anastomosis, allowing a proper decompression that protects the anastomosis area, without requiring any surgical reintervention. Anastomotic colorectal surgery is thus safer with certain benefits for patients.

EDITORS POINT OF VIEW

Challenges of the next normality

Victor L. Purcarea, Daniel O. Costache

At the beginning of last year, Professor Eliot Sorel continued to plead for a successful exit from the devastating pandemic, highlighting, among other aspects, the role played by the creative integration of the artificial and human intelligence in accelerating post-pandemic innovations (Sorel E. COVID-19 Vaccines, Accelerated Innovations, and 21st Century Social Contracts Challenges. World Soc Psychiatry. 2021; 3:7). At the same time, a study conducted by the McKinsey Global Institute (part of McKinsey & Company, involved in business and economic research) highlighted the *three groups of consumption and business trends accelerated by COVID-19*: distance working and virtual interactions, e-commerce, and digital transactions, as well as implementation of automation and AI (McKinsey Global Institute, The future of work after COVID-19, The post pandemic economy, Executive summary, February 2021).

In an article published by McKinsey & Company in November 2021 (Bujor, M., Cierkowska, A., Dorling, G., Dragan, R., Filip, A., Remes, J. and Vukojevic, M. How prioritizing health can be a prescription for Romania's prosperity, McKinsey & Company, November 2021), the aspects highlighted were: *the hard lessons learned in the context of the COVID-19 pandemic*, the opportunity of promoting health and welfare, taking into account the weaknesses of the health system and the indissoluble relationship between health and economy; a number of encouraging lessons on the ability to respond effectively in the context of the crisis (rapid development of COVID-19 vaccines, adoption of digital health tools and companies implementation of rapid operational changes in order to adapt to the pandemic).

In December 2021, in an episode from the McKinsey podcasting about health care, the executive director of Datavant company (which is about to become one of the world's largest healthcare data ecosystems, enabling patients, providers, payers, healthcare data analysis companies, patient applications, government applications and institutions dealing with living organisms and life processes *to exchange patient data safely*), Pete McCabe, talked about *current challenges: data fragmentation and access, the benefits of tokenization* (process of substituting a sensitive data element with a non-sensitive equivalent, called token; tokens can be individual words, phrases and even whole sentences; the process allows the division of a sequence into pieces, some characters, such as punctuation marks, being removed), *value-based care and the need for neutrality* (Reddy, P., 2021. How can healthcare unlock the power of data connectivity? McKinsey & Company, Healthcare Systems & Services Practice, December 2021). According to McCabe, for example, innovative technologies, such as tokenization, can close data connectivity gaps (this connectivity places together disparate data sets and applications, including data from different identity spaces, allowing collaboration between different parts with data control, ensuring secure and efficient activation across the wider ecosystem); the foundation of value-based care requires data and this can be as good as the basic data that supports it; value-based care is just the beginning of potential leadership, so, if the internet can recommend a piece of clothing based on consumer's buying history, why would not a doctor be able to recommend a treatment based on a holistic view of individual life data of a patient?

Also in December 2021, CB Insights highlighted the agile adaptation of technology giants such as Amazon, Microsoft, Google, and Apple to the challenges in the pharmaceutical industry caused by the COVID-19 pandemic, respectively, *the answer of these large technology companies materialized in building technology for drug discovery, clinical trials, production, and supply chains, as well as patients' remote monitoring and their health records* (CB Insights a, 2021. The Big Tech In Pharma Report: How Amazon, Microsoft, Apple, And Google Are Capitalizing On The Digital Transformation, December 14, 2021). Those who are familiar with the field are also accustomed to the developments that allow patients to manage their own health based on both data records from the Electronic Health Record/EHR, containing the medical history based on the physician's records (including lab results and care conclusions), and patient-generated data (such as symptoms). According to CB Insights, *the above-mentioned technology giants make the most of their expertise in software, data, and artificial intelligence to capitalize opportunities along the value chain* (its management considers the bottom-up flow, that is from the consumer/patient to the source; the value chain management 4.0 means generating and keeping value throughout the chain, using the technology usually associated with industry 4.0 everywhere, not just in the factory). CB Insights insists that *reducing the cost of drug development is a top priority, a way of making this possible by using digital solutions* (software), and, in this context, big technology companies pay close attention to the digital transformation of the pharmaceutical industry: Amazon builds the drugstore of the future using its supply chain in order to create a customer experience similar to its e-commerce business; Microsoft enters the pharmaceutical market with SaaS healthcare solutions and partnerships with the already existing players; Google uses patient data and artificial intelligence expertise to build drug research and development capabilities; Apple uses its hardware and user database to its advantage, in order to build a secure, centralized location for patient health data (CB Insights b, 2021. Apple's greatest contribution, Healthcare Insights, Thu 23/12/2021 14:04).

Obviously, the COVID-19 pandemic forced the reimagining of all aspects related to healthcare services, with *considerable changes in telehealth, digital therapy, and medical devices* (CB Insights c, 2021. Our Top 2021 Healthcare Reports, December 21, 2021). Thus, healthcare providers have considered innovative solutions to improve clinical workflows and decided for a wide range of remote care options (from consultations to therapies and mental health support). A confirmation of this concern in our increasingly digital world is the evolution of global funding for healthcare amid the continuing waves of COVID-19 pandemic (which reached $97,8 billion in the third quarter of this year, a figure that keeps on growing, breaking the total record of 2020 by 21%).

There is no doubt that the use of information and communication technologies in medicine (as well as in other medical professions, in order to manage disease and health risks and to promote well-being) will continue to play an increasingly critical role in improving health care. But, digital transformation (generally understood only as a shift to supporting more business functions with the help of technology) does not mean just switching to digital methods of communicating with potential clients (patients). "Digital" does not only refer to technology in business models, it refers just as much to people and mentalities, to humanization, as the effects of the COVID-19 pandemic have changed the habits of clients/users, and the providers of health care services have been forced to adapt their strategies on the continuous improvement of their relationship with the patient.

This improvement also depends on optimizing operational efficiency throughout the supply chain, to provide the client/ patient a frictionless, convenient, and personalized decision in all aspects, for a better understanding of all the moments (and even the micro moments) of the interaction in the "digital" space. The essence of an agile transformation is the reimagining of an organization as a network of high-quality teams, supported by an efficient and stable backbone of strategy, structure, processes, people, and technology. Digital adoption means reaching a state in which users gain the ability to use digital tools to the fullest and in the way they are intended, software adoption being just a part of the digital adoption process.

VARIA – Letter to Editor

Challenging of COVID-19 crisis in the Emergency Department

Hassan Goodarzi[1], Sardollah Mahmoodi[1]

Dear editor,

The outbreak of coronavirus disease 2019 (COVID-19) is quickly spreading in the world [1]. The COVID-19 has negatively affected the standard services presented in the emergency department (ED). The ED must provide health services to large populations with various health problems. COVID-19 conditions raised pressure on the limited resources in ED and caused interruptions in preliminary treatment. Recently, evidence verified that there are increased rates in emergency healthcare services usage because of the raising traumatic injuries. In the COVID-19 crisis, the statistics and causes of trauma injuries patients were dramatically changed and because of the attendance of further family memberships at household domestic injuries and burning in children were increased [2].

Healthcare services overcrowding has negative consequences to the patients, the healthcare services, and the population. Overcrowding of the healthcare services could also hurt standards services preparation [2]. Moreover, in an outbreak of a communicable disease such as COVID-19, overcrowding has specific negative consequences on controlling and prevention of expansion of diseases. Overcrowding in ED could be the trigger to spread COVID-19 more rapidly. Furthermore, the structure in many EDs is insufficient for facing with overcrowding of patients, causing unsatisfactory situations while people are anticipated to have prolonged for suitable treatment in ED. Also, in many EDs maybe there are inadequate clinical spaces to facilitate evaluation and therapy of cases with confidentiality. Also, there are a high number of emergency patients and the seriousness of their conditions has hindered the timely admissions of emergency patients and cause overcrowding of healthcare services. The increased high non-urgent patients that were scared from coronavirus flow to the hospitals were other identified factors that contributed to the hospital crowding. These circumstances have adversely affected the quality of services and performance.

Following the quick spread of the COVID-19 crisis in the world, unfortunately, there is a limitation to access to supplies such as gloves, medical masks, respirators, hand washers, etc. However, a shortage of personal protective equipment could endanger the general population and as well as healthcare workers. Governments and healthcare administrators must performance rapidly to provide supplies.

Healthcare workers involved with COVID-19 cases in ED were commonly under high pressure. Maintaining the mental health of Healthcare workers in ED is very crucial to manage COVID-19 cases. Administrators must have care to the work stress and the associated causes of the Healthcare workers.

A suitable registry system in ED could help for better management and follow-up of COVID 19 cases and also it could help researchers for better understanding and studying about various aspects of COVID 19 during a long time follow-up after treatment.

Characteristics and complications of supernumerary permanent teeth in a sample of patients examined in a university pedodontics clinic

Mihaela Tănase[1], Aneta Munteanu[1], Ioana A. Stanciu[1], Elena C. Coculescu[2], Carmen Nicolae[2], Gabriela D. Bălan[3]

Abstract: *Aim. The assessment of distribution of supernumerary permanent teeth (SPT) and the disturbances caused by them.*

Material and method. Cross-sectional study upon a sample of 85 children (58 boys) aged between 3 and 18 years (mean age=9.08±3.09 years) with at least one SPT. Were analyzed: patients' distribution according to gender, age and number of dental units; SPT distribution according to arch and topography and also the disturbances noticed.

Results. a) boys:girls ratio=2.14:1; b) the 85 patients had 107 SPT, mean number=1.25; c) 76.47% of patients had one SPT; d) 89.72% of SPT were on maxillary arch, maxilla:mandible ratio = 8.7:1; d) 92.52% of SPT were localized in anterior region, anterior:posterior region ratio = 12.3:1; e) mesiodens –71.96%, supernumerary lateral incisor – 19.62%; f) disturbances caused by SPT: ectopic eruption of permanent teeth – 36.47%; delay or failure of eruption of permanent teeth – 21.17%; crowding – 20%.

Conclusions. 1. Supernumerary teeth were most frequent noticed in boys, in maxillary anterior region. 2. Most often they caused eruption disturbances of permanent teeth.

Keywords: *supernumerary permanent teeth, distribution, complications*

INTRODUCTION

SPT are defined as any tooth or odontogenic structure that is formed from a tooth germ in excess of the usual number of teeth for any region of the dental arch [1, 2]. In permanent dentition, this dental anomaly is 5 times more frequent than in primary dentition, the prevalence values reported ranging from 0.1 to 6% [2, 3].

In Romania, there are few recent studies have been carried out on the SPT [4]. These focused more on the distribution of SPT, but less on local disturbances caused by their presence. This study is important because it helps to identify early signs of the presence of SPT and thus prevent loss of permanent teeth or further complications.

The aim was to analyze the distribution of SPT and to assess the disturbances produced by them, in a group of children examined and treated in a University Pedodontics Clinic.

MATERIAL AND METHODS

A retrospective cross-sectional study was conducted on a sample of 85 children (58 boys, 27 girls) aged 3 to 18 years (mean age = 9.08 ± 3.09 years), with at least one SPT. Children were examined in the Pedodontics Department,

ivan.aneta@yahoo.com

Faculty of Dental Medicine, Carol Davila University, Bucharest. Criteria for choosing the study sample were: patients aged up to 18 years old, without genetic diseases, chronic diseases or lip-palate clift. Pre-existing conditions, such as cardiac pathology, were evaluated [5-8].

Data on dental status were obtained from dental records of patients examined and treated by a single dentist. The diagnosis of the number anomaly was made on clinical and radiological examinations. For each patient diagnosed with this anomaly were noted: age, gender, permanent teeth erupted, presence, position and shape of the SPT and disturbances produced by them.

The data obtained were collected and processed using SPSS-version 20.0 for Windows (SPSS Inc, Chicago, IL, USA).

The aim of the research was to analyze: the distribution of patients with SPT according to sex, age and number of affected teeth; the distribution of SPT according to the affected arch and the topography of the tooth, and the disturbances produced.

RESULTS AND DISCUSSION

Sex distribution of the sample

The percentage of boys diagnosed with this anomaly was 68.23% and for girls - 31.77%. The boys:girls ratio was 2.14:1.

It was noted that in 3 male patients it was observed that the SPTs were associated with the congenital absence of other permanent teeth (Hyper-Hipodontia syndrome).

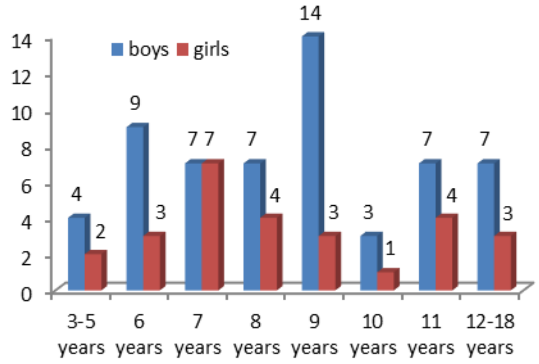
Age distribution of the sample

Most often, the number anomaly was noticed at the age of 9 years (Figure 1).

Patients' distribution according to the number of affected teeth

The 85 children had a total of 107 teeth, with an average number of 1.25 teeth. Most commonly patients had a single permanent tooth in excess – 65 (76.47%), 18 (21.17%) had 2 SPT and only 2 patients (2.35%) had 3 SPT.

Figure 1. Age distribution of the sample according to the age at which the anomaly was diagnosed



SPT distribution according to their topography

Most of the SPT were in the upper arch, in the front area (Table 1). Maxilla: mandible ratio was 8.7:1, and the anterior: posterior area ratio was 12.3:1. Note that multiple SPT have only met in the upper front area.

Table 1. Distribution of SPTs according to their topography

	Maxilla		Mandible		Total	
	n	%	n	%	n	%
Anterior	92	85.98	7	6.54	99	92.52
Posterior	4	3.74	4	3.74	8	7.48
Total	96	89.72	11	10.28	107	100

SPT distribution according to the type and shape of the teeth

The conical-shaped mesiodens was the most common oversized tooth, followed by lateral incisor with a similar shape to the normal-series tooth (Table 2).

Table 2. Distribution of SPT according to type and morphology

Shape	Supplementary	Conical shape	Tuberculate shape	Odontoma	Total	
					n	%
Mesiodens	9	47	17	4	77	71.96
Lateral incisor	19	1	1	0	21	19.62
Parapremolar	4	0	0	0	4	3.73
Paramolar	1	2	0	0	3	2.80
Distomolar	1	0	0	0	1	0.93
Canine	0	0	1	0	1	0.93
Total	33	50	19	4	107	100

Of the 77 mesiodens, 12 (15.58%) were inverted, being discovered by chance on the X-rays.

Distribution of the disorders caused by SPT

Most of mesiodens determined the deflection of the permanent tooth eruption from the normal series, while the lateral incisors caused or worsened the crowding (Table 3).

Table 3. Disorders caused by SPT

Disturbances	Mesiodens	Lateral incisor	Parapremolar distomolar	Para-molar	Canine	Total	
						n	%
Ectopic eruption	29	1	0	1	0	31	36.47
Failed eruption	16	2	0	0	0	18	21.17
Crowding	2	15	0	0	1	17	20
No consequences	8	2	0	0	0	17	20
It can't be appreciated	2	0	5	2	0	2	2.35
Total	77	21	5	3	1	85	100

DISCUSSIONS

In the literature there are numerous studies of this anomaly that analyze their frequency, shape variations and disturbances that can be associated with different population groups. Most studies were conducted on samples of patients from orthodontic clinics. But early diagnosis of SPT helps to achieve an appropriate treatment plan and to prevent further complications.

In permanent dentition, the prevalence of the disease varies between 0.1 and 2.1% in Caucasian, between 2.4 to 6% in Chinese, Japanese and black Americans [2, 5]. In Romania, the prevalence value was 3.04% [4].

Analyzing the distribution by sex, the boys:girls ratio of the SPT was 2.14:1. This result is similar to that reported by numerous studies conducted in international groups of children or adults [9-14]. Instead, Bäckman and Wahlin (2001) found a predilection of SPT in females [15], which was highlighted by Mitchell (1989), who found a female:male ratio of 2:1 [16]. Unlike them, Dominguez and Mendoza (1995) did not discover any difference between the sexes [17].

Rani et al. (2017) noted that SPT are more frequently diagnosed in people aged the first 3 decades of life [2]. In a study conducted by analyzing 2241 X-rays, Salcido-García et al. (2004) found that from the total number of patients with SPT 47.6% were in the third decade of life, followed by those in the first decade of life in a percentage of 28.5% [18]. This study, conducted on a group of children, showed that the average age to which this anomaly was diagnosed was 9 years. Also, Alberti et al. (2006) conducted a study on a lot of patients aged between 6 and 10 years and concluded that the interval for early diagnosis and prevention of malocclusions caused by hyperdontia is around the age of 9 [13]. More than ¾ between children had one extra tooth, resulting similar to values reported by other researchers [9-14].

Regarding the topography, the SPT were identified in the present study of approximately 90% in the upper jaw, a percentage similar to that reported by Zhu et al. [19] or Hattab et al. [20]. Instead, Fernández-Montenegro et al. (2006) [21] found that 74.5% of the SPT were at the maxilla, while Leco-Berrocal et al. (2007) – a percentage of 79.2% [9].

In the present study, 92.52% of the SPT were located in the front area. Other studies report in adult populations a higher frequency of SPT in the posterior jaw area. It is agree that in children the most frequent location is in the front area, and in adults in the posterior area [9].

In the group studied in the Pedodontics Clinic from Bucharest, mesiodens appeared in 71.96% of cases, followed by lateral incisor (19.62%). Also, Fernández-Montenegro et al. (2006) found that mesiodens was the most commonly diagnosed, followed by parapremolar and distomolar [21], Salcido-Garcia et al. (2004) found the order: mesiodens, parapremolar and lateral incisor [18] and Bereket et al.: mesiodens, distomolar, parapremolar [10]. On the other hand, in the study of Khandewal et al. (2018), parapremolars were most commonly met [14], and at Leco-Berrocal et al. (2007) [9] and Rani et al. (2017) – distomolars [2].

Most of the authors found that the conical shape is the most common, this fact also emerged in the present research [10-12, 14, 21, 22]. In second place, supplementary teeth were observed, as in the study conducted by Fernandez-

Montenegro et al. (2010) [21], while Shah et al., and Schmukli et al. (2010) found the tuberculate shape [11, 22].

As far as the consequences are concerned, in this study in most cases the deflection of the teeth eruption of the normal series was encountered, followed by the failed of permanent teeth eruption and crowding. Leco-Berrocal et al. reported that the most common complications were mechanical accidents, namely the deflection of adjacent teeth -39%, root resorption -12.5% and failed of eruption-4.1%, but also 19% follicular cysts [9]. Rajab and Hamdan were observed that 51.47% of meziodentes failed the eruption of permanent incisors [12].

No consequences were observed in 20% of cases. Instead, Fernández-Montenegro et al. (2006) and Bereket et al. (2015) found the lack of any consequences in a large percentage – 57.9%, respectively 61.64% [10, 21].

Most of the results from the present study were similar to the values reported in the literature. Differences may be caused by racial type and the mean age of the sample.

CONCLUSION

1. Hiperdontia was seen more frequently in boys compared to girls (2.14:1).
2. The SPT have been located most frequently in the upper front area.
3. The most common type of SPT was mesiodens (71.61%) followed by the upper lateral incisor (19.62%).
4. In most cases, the SPT resulted in the deflection of a tooth from the normal series.

Chest CT-scan findings in COVID-19 patients: the relationship between the duration of symptoms and correlation with the oxygen saturation level

Aryaa Qaasemya[1], Hojjatollah Khajehpoura[1], Hadi E. Gouvarchin Galehb[2], Ruhollah Dorostkarb[2], Ehsan Assadollahic[3], Soudabeh Alidadid[4]

Abstract: *Purpose: This study is carried out to evaluate the diagnostic value of using common features of computed tomography (CT) imaging in COVID-19 disease, and to assess the relationship between blood oxygen saturation level and severity of CT findings.*

Materials and Methods: In this retrospective study, the chest CT of 173 test-confirmed COVID-19 patients have been evaluated to determine the patterns of involvement in multiple phases of illness. Then, the correlation between the severity of lung involvement and oxygen saturation levels has been assessed.

Results: The chest CT results show that 87.6% of patients had GGO, which was the most common pattern in our findings. 83.8% of patients had bilateral lung involvement with the dominant multifocal and peripheral distribution. peribronchovascular involvement was also a common finding in our study (47.2 %). we found predominantly peribronchovascular view in 3 patients (1.7%), pleural effusion in 4 patients (2.3%), lymphadenopathy in 10 patients (5.8%), the tree in the bud in one patient (0.6%), and nodules in 4 patients (2.3%). We also found that GGO is the most common pattern during the early phase of the disease (97.4% of early phase cases). However, in the intermediate and late phases, consolidation and crazy paving patterns are more common. Moreover, our findings indicate that there is a significant relationship between oxygen saturation level and Total Severity Score, with the exclusion of the young adult patients (20-40 years).

Conclusion: Relying on chest CT-scan findings apart from the oxygen saturation level is sufficient for the diagnosis and management of patients with COVID-19 pneumonia.

INTRODUCTION

Coronaviruses as part of the coronaviridae family are nonsegmented, enveloped, positive-sense, and single-strand ribonucleic acid viruses [1]. This is the seventh known coronavirus to infect humans [2]. Two other notable examples of this coronaviridae family include severe acute respiratory syndrome (SARS) and the Middle East respiratory syndrome (MERS). SARS began spreading in southern China

and resulted in 774 deaths out of 8,098 infected individuals in 29 countries from November 2002 through July 2003 while MERS originated in Saudi Arabia and caused 848 deaths among 2,458 individuals in 27 countries through July 2019 [3, 4].

The number of confirmed COVID-19 cases continues to grow rapidly in the world. The recent outbreak of the novel coronavirus (COVID-19) began in December 2019 in Wuhan, the capital of central China’s Hubei province, and has led to a major pandemic [2, 5]. Widespread human-to-human transmission has resulted in 5,240,900 cases worldwide with 338,700 deaths as of May 23, 2020 [6].

Patients infected with this novel COVID-19 virus manifested with symptoms of severe pneumonia, including fever, fatigue, dry cough, and acute respiratory distress. 2019-nCoV caused clusters of fatal pneumonia with clinical presentation greatly resembling SARS-CoV. Patients infected with 2019-nCoV might develop acute respiratory distress syndrome, have a high likelihood of admission to intensive care, and might die. The cytokine storm could be associated with disease severity. More efforts should be made to know the whole spectrum and pathophysiology of the new disease [7].

According to available guidelines, the diagnosis of COVID-19 should be confirmed by reverse-transcription polymerase chain reaction (RT-PCR) or gene sequencing of respiratory or blood specimens. However, the RT-PCR has shown detection rates as low as 30% to 60% and also false-negative results at the initial presentation while this technique requires specific sample collection protocol, preparation, and particular facilities that have prevented accurate and fast results being available for further diagnosis [8]. These limitations in diagnosis and treatment subsequently result in a higher rate of infection demanding an effective strategy for the early diagnosis of COVID-19.

Radiological imaging is known as a critical assessment technique for the evaluation of severity and disease progression in upper and lower bronchial disorders such as COVID-19 infection. Among variable imaging techniques, Computed Tomography (CT) scans have shown promising potential in COVID-19 case ascertainment [9, 10]. Chest spiral CT is a crucial diagnosis test for COVID-19 disease, which is used to assess the severity of lung involvement in COVID-19 pneumonia. [10, 11]. A variety of imaging patterns in chest CT-Scan have been described in other studies such as bilateral lung opacities in infected patients and described lobular and subsegmental areas of consolidation as the most typical findings. Other investigators examined chest CTs in 21 infected patients and found high rates of ground-glass opacities and consolidation, sometimes with a rounded morphology and peripheral lung distribution [12, 13]. CT abnormalities might predate rtRT-PCR positivity in symptomatic and asymptomatic patients who were subsequently tested positive according to their rtRT-PCR results [14, 15, 16].

In this study, we characterize chest CT findings in 173 patients infected with COVID-19 and conformed with rt-RT-PCR in relationship to the time between symptom onset and the initial CT scan. Also, we evaluate the correlation between O_2 saturation and the severity of the lung involvement in chest CT scans.

MATERIAL AND METHODS

In this retrospective study from March 4, 2020, until March 10, 2020, 173 adult patients admitted to Baqyatollah hospital in Tehran province in Iran with confirmed COVID-19 infection and undergone chest CT scans were enrolled in our study. There have been no exclusion criteria considered in this research.

Confirmation of the disease was performed through laboratory testing for COVID-19 with real-time reverse transcriptase-polymerase chain reaction (rRT-PCR) of respiratory secretions obtained by bronchoalveolar lavage, endotracheal aspirate, nasopharyngeal swab, or oropharyngeal swab which were positive for all patients. The rRT-PCR test kit used in this study was provided by SinaPure TM viral (Tehran-Iran).

All patients were imaged with a 3.5-mm slice thickness CT on a Siemens Emotion 16 scanner (Siemens Healthineers; Erlangen, Germany). All scans were performed without intravenous contrast injections in the supine position during end inspiration.

In addition to the age [17] and gender parameters, other information such as the number of days between the onset of the symptoms and date of first chest CT-scan were recorded for further analysis. This disease changed rapidly at the early stages [18], so in this study, if the time interval between the first clinical symptom and CT was two days or less, the patient was considered to have been imaged in the “early” phase of the illness. If the time interval was between three and five days, the patient was considered to have been imaged in the “intermediate” phase of the illness. If the time interval was between six and 12 days, the patient was considered to have been imaged in the “late” phase of the illness.

Oxygen saturation of patients was also measured in the pressure of the air room once they were admitted to the hospital.

All CT images were reviewed by two trained and experienced radiologists with 10 years of experience. Imaging was reviewed independently and reported after the final decisions were made in consensus. Negative control cases were also examined.

For each patient, the chest CT scan was evaluated for the following characteristics:
(1) Presence of ground-glass opacities,
(2) Presence of consolidation,
(3) Laterality of ground-glass opacities and consolidation (unilateral or bilateral),
(4) Number of lobes affected where either ground-glass or consolidative opacities were present,
(5) Degree of involvement of each lung lobe in addition to the overall extent of lung involvement measured through a "total severity score",
(6) Presence of nodules,
(7) Presence of a pleural effusion,
(8) Presence of thoracic lymphadenopathy (defined as lymph node size of ≥10 mm in short-axis dimension),
(9) Distribution of the disease (categorized as a unifocal disease, multifocal disease, peribronchovascular disease, peribronchovascular predominant disease, or peripheral disease),
(10) Other abnormalities including opacities with a crazy-paving pattern, opacities with intralesional cavitation, the tree in bud appearance, and vascular enlargement were noted.

The ground-glass opacification was defined as hazy increased lung attenuation with preservation of bronchial and vascular margins, whereas consolidation was defined as opacification with the obscuration of margins of vessels and airway walls [19].

Regarding the total severity score, each of the five lung lobes was assessed for degree of involvement and classified as none (0%), minimal (1 - 25%), mild (26 - 50%), moderate (51 - 75%), or severe (76 - 100%). No involvement corresponded to a lobe score of 0, minimal to a lobe score of 1, mild to a lobe score of 2, moderate to a lobe score of 3, and severe to a lobe score of 4. An overall lung total severity score was reached by the sum of the five lobe scores (range of possible scores, 0 - 20). Then the correlation between "Total Severity Score "and O_2 saturation was calculated.

RESULTS

This study was conducted based on a CT-scan data set consists of 110 male and 63 female patients with an average age of 63± 3.94 years and the age range between 6 to 86 (Table 1).

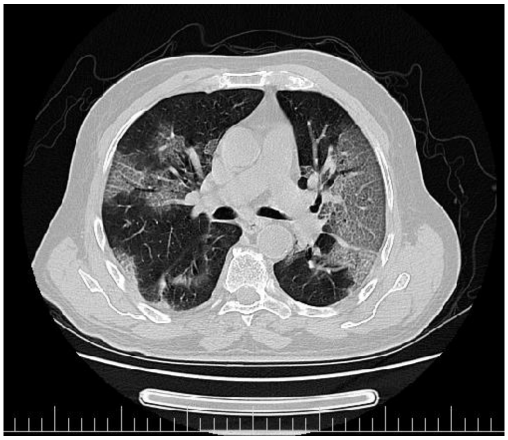
Table 1: Patient characteristics

Gender	All patients N= 173	Early* (0-2 days) N= 39	Intermediate (3- 5 days) N=113	Late (6-12 days) N=21
Men	110 (63.5)	24 (61.5)	71 (62.8)	15 (71.4)
Women	63 (36.5)	15 (38.5)	42 (37.2)	5 (28.6)
Age (years)				
Mean	53.6	47.28	53.96	58.95
Range	7 - 86	21 – 85	7 – 86	36 – 85
SD	3.94	15.29	13.55	11.28
O_2 saturation				
Mean	89.44	93.05	89.27	83.67
Range	67 – 98	89 – 98	74 – 97	67 – 94
SD	4.76	2.82	3.58	6.88

**Early, intermediate, and late refer to time from symptom onset to time of the chest CT scan;*
SD – standard deviation.
Note: Numbers in parentheses are percentages.

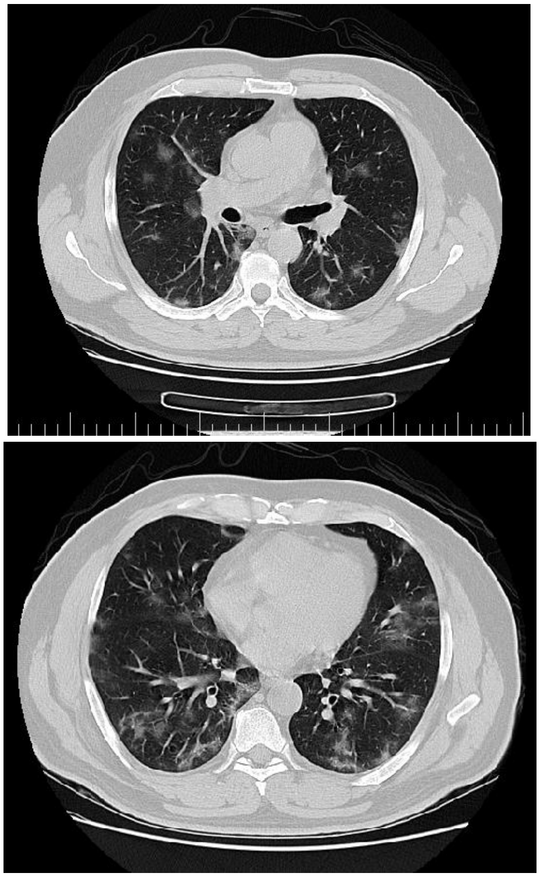
According to the results, one-hundred and forty-four patients have shown multifocal bilateral lung involvement. Among these patients, 78 patients (54.2%) had only GGO (without consolidation), 14 patients (9.7%) had the only consolidation (without GGO) and 51 patients (35.4%) had both of them.

Figure 1: An axial CT image obtained without intravenous contrast in an 85-year-old male shows a "crazy-paving" pattern as manifested by bilateral ground-glass opacification with interlobular septal thickening with intralobular lines.



In this study, different types of lesions have been observed in the 173 patients with confirmed COVID-19 disease. These lesions are GGO (Figure 1, Figure 2, Figure 3), consolidation (Figure 3), crazy paving (Figure 1) and vascular enlargement (Figure 4), which are observed in 151 patients (87.6%), 77 patients (44.5%), 23 patients (13.3%) and 106 patients (61.3%), respectively.

Figure 2: An axial CT image obtained without intravenous contrast in a 52-year-old male shows bilateral peripheral and peribronchovascular ground-glass opacities with round morphology.



The number of affected lobes can vary in different patients. Among the 173 patients, 23 patients (13.3%) showed lung opacities in one lobe, 14 patients (8.1%) in two lobes, 13 patients (7.5%) in three lobes, 23 patients (13.3%) in four lobes, and 99 patients (57.2%) in all five lobes. Moreover, the right upper lobe of 133 (76.9%) patients, the right lower lobe of 151 patients (87.3%), the left upper lobe of 133 patients (76.9%), and the left lower lobe of 153 patients (88.4%) were involved.

145 patients out of 173 total patients (83.8%) had bilateral and 145 patients (16.2) had unilateral lung involvement as shown in Table 2. The average total severity score (ranged from 1 to 20) was 5.75±3.87. This study revealed that the relationship between the patient's age and the total severity score is statistically significant ($p<0.001$ and the correlation coefficient is 0.29).

Also, Table 2 shows the lesion distribution. According to this table, 21 patients (12.1%) had shown unifocal involvement, 153 patients (88.4%) had multifocal involvement, 170 patients (98.3%) had peripheral involvement and 82 patients (47.2%) had peribronchovascular involvement.

Figure 3: An axial CT image obtained without intravenous contrast in a 56-year-old male shows bilateral and peripheral ground-glass opacities with dominant consolidation.

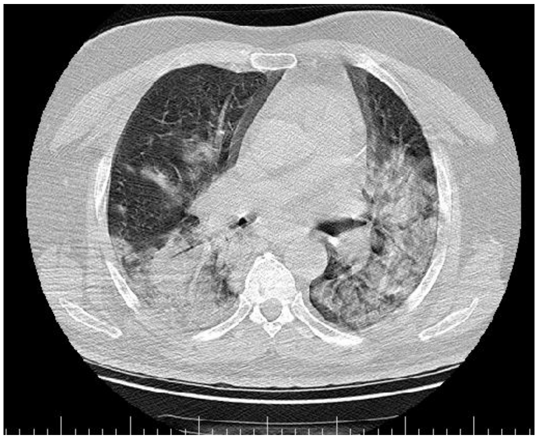


Figure 4: An axial CT image obtained without intravenous contrast in a 60-year-old female shows unilateral opacification with the tree in bud appearance which is a very rare presentation of COVID-19 pneumonia. Vascular enlargement is also noted which is a common finding.

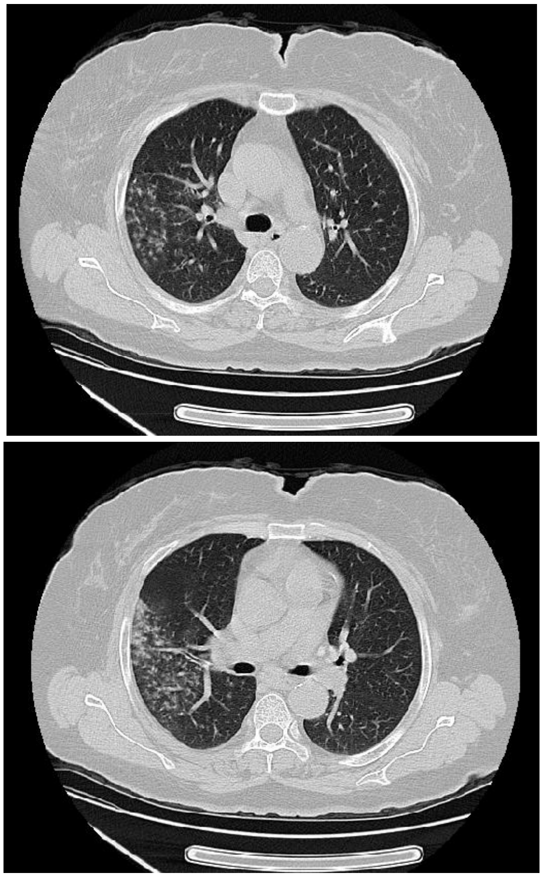

Table 2: Findings on chest CT in 173 patients

Ground-glass opacities and consolidation	
absence of both ground-glass opacities and consolidation	0 (0)
presence of either ground-glass opacities or consolidation	173 (100)
presence of ground-glass opacities without consolidation	96 (55.5)
presence of ground-glass opacities with consolidation	55 (31.8)
presence of consolidation without ground-glass opacities	22 (12.7)
Number of affected lobes	
0	0 (0)
1	23 (13.3)
2	14 (8.1)
3	13 (7.5)
4	23 (13.3)
5	99 (57.2)
more than 2 lobes affected	149 (86.6)
bilateral lung disease	145 (83.8)
Frequency of lobe involvement	
Right Upper Lobe	133 (76.9)
Right Middle Lobe	108 (62.4)
Right Lower Lobe	151 (87.3)
Left Upper Lobe	133 (76.9)
Left Lower Lobe	153 (88.4)

Note: Numbers in parentheses are percentages.

We also examined all patients to find any lesions unrelated to the COVID-19.

According to this examination, we found predominantly peribronchovascular view in 3 patients (1.7%), pleural effusion in 4 patients (2.3%), lymphadenopathy in 10 patients (5.8%), the tree in the bud in one patient (0.6%), and nodules in 4 patients (2.3%).

The cavity was not observed in any evaluated cases.

The results from the classification of patients based on the period between the early symptoms' observation and the CT-scan imaging showed that the number of ground-glass's opacity is significantly different within these three groups (p = 0.003), i.e., the GGO is observed much more in the early phase patient's group compared to the two other groups.

The GGO has been found in 97.4% of the early phase patient group, 87.6% of the intermediate phase patient group, and 66.7% of the late-phase patient group (Table 3, Figure 5).

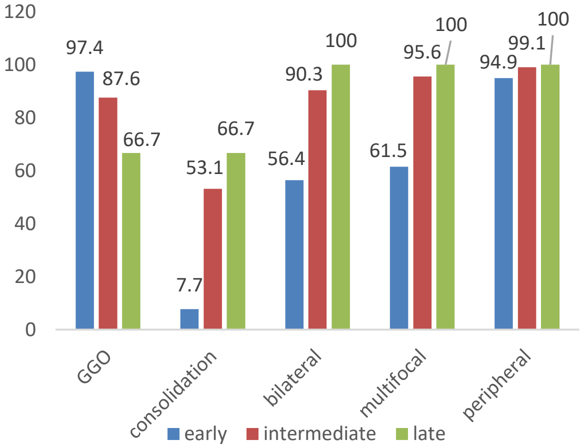
The numbers of consolidation and crazy paving appearance are significantly different within these three groups (p <0.001). The number of consolidation and crazy paving appearance is increased by increasing the time elapsed from early symptom onset to CT-scan imaging.

Table 3: Findings on chest CT in patients categorized by infection time course

	Early (0-2 days)	**Intermediate (3- 5 days)**	**Late (6-12 days)**
ground-glass opacities	38 (97.4)	99 (87.6)	14 (66.7)
consolidation	3 (7.7)	60 (53.1)	14 (66.7)
lung opacities in 1 lobe	16 (41.0)	7 (6.3)	0 (0)
lung opacities in 2 lobes	8 (20.5)	6 (5.4)	0 (0)
lung opacities in 3 lobes	2 (5.1)	9 (8.0)	2 (9.5)
lung opacities in 4 lobes	7 (17.9)	16 (14.3)	0 (0)
lung opacities in 5 lobes	6 (15.4)	74 (66.1)	19 (90.5)
bilateral lung involvement	22 (56.4)	102 (90.3)	21 (100)
mean total severity score	2.59	5.87	10.95
"crazy-paving" pattern	1 (2.6)	12 (10.6)	10 (47.6)
peripheral distribution	37 (94.9)	112 (99.1)	21 (100)
pulmonary nodules	2 (5.1)	2 (1.8)	0 (0)
pleural effusion	0 (0)	3 (2.7)	1 (4.8)
lymphadenopathy	0 (0)	10 (8.8)	0 (0)

Note: Numbers in parentheses are percentages.

Figure 5: Frequency of selected chest CT findings as a function of time course from symptom onset



The observation within the early phase patient's group shows that consolidation and crazy paving appearance have been observed among 7.7% and 2.6% of the group, respectively. Besides, observation of the intermediate phase patient's group indicates that 53.1% and 10.6% of the patients showed consolidation and crazy paving appearance, respectively. Finally, in the late phase patient's group, 66.7% of consolidation, and 46.6% of crazy paving appearance have been observed (Table 3, Figure 5). Generally, there is a significant relevance between the time elapsed from early symptom onset to CT-scan imaging and the severity of lung involvement based on SST (p-value<0.001). Moreover, the severity of lung involvement is higher in the cases with the longest elapsed time from symptom onset to CT-scan imaging.

The level of oxygen (O_2) saturation has been measured for all patients before the CT-scan imaging. The average level of oxygen saturation was 89.01% (with a range of 67 to 97 and a standard deviation of 4.16). It is observed that there is a significant relevance between the oxygen saturation level and TSS ($p<0.001$ and correlation coefficient is -0.587); but there isn't any significant relevance between O_2 saturation and TSS within the age group of 20-40 years old.

DISCUSSIONS

COVID-19 has turned into a global challenge and a historic pandemic resulting in 2,019,088 cases worldwide with 131,886 deaths as of April 16, 2020 [6]. Although the rtRT-PCR testing of respiratory secretions or blood samples is the definitive diagnosis of COVID-19, the likelihood of false-negative cases has made chest CT-scan one of the important tests for relatively early diagnosis of COVID-19 pneumonia. Various imaging patterns have been reported in previous studies conducted on COVID-19 pneumonia, which varied in their importance.

In this study, we examined and classified the chest CT-scan imaging features of 173 patients with a definitive diagnosis of COVID-19 based on the rtRT-PCR test. The most common findings were ground-glass opacity (87.3%), vascular enlargement (61.3%), consolidation (44.5%) and crazy paving pattern (13.7 %). The majority of cases had bilateral (83.7%) and multifocal (88.4%) involvements. These findings are largely consistent with previous studies [12, 13], which indicates that the ground-glass view with or without pulmonary consolidation and in the forms of the bilateral peripheral and multifocal pattern are the diagnostic hallmarks of COVID-19 pneumonia.

Although the majority of patients had peripheral involvement, many of them had concomitant central or peribronchovascular involvement (47.7%). This distribution pattern was more common in the present study than in previous studies [13, 20], since the majority of our patients were in either the intermediate or the late-phase of the onset of the symptoms. It is worth noting that the public access to diagnostic-medical equipment, such as CT-scan, is lower in Iran than in the developed countries. Therefore, many infected individuals remained undetected in the early phases of the COVID-19 pandemic and thus had a late visit, which justifies more severe pulmonary involvement in the present study. Based on our findings, although the bilateral peripheral and multifocal involvements are the hallmarks of this disease, nevertheless, a portion of our patients had unilateral and even unifocal involvement, specifically in the early days of the onset of the symptoms. Besides, three patients and one patient have mildly and moderately pleural effusion, respectively. Previous studies highlighted that pleural effusion is detrimental to COVID-19 diagnosis. The present study confirms this finding since all of these four patients had congestive heart failure (CHF). Therefore, the authors recommend that in addition to examining CT-scan results for COVID-19, the underlying diseases of the patients should also be considered.

In total, 5.8% of the patients had mediastinal lymphadenopathy, which was higher than other studies [13, 21, 22]. It should be pointed out that lymphadenopathy can be seen in patients with heart failure, mediastinal infections, and/or cancer. In the present study, all 10 patients with lymphadenopathy had concomitant heart failure, based on their medical history and imaging results. Therefore, further studies with a more accurate design are required on a larger population for examining the underlying diseases to establish whether this type of involvement can be a marker of COVID-19.

In our study, the relationship between the imaging features and the elapsed time from early symptoms onset to CT-scan imaging shows that at the "early phase" of the disease the ground-glass has been the dominant imaging view, while by moving towards the intermediate and late phases of the disease, the intensity of the ground-glass opacity reduces, and instead the appearance of consolidation and crazy paving pattern increases. It is also observed that the consolidation view alone, without ground-glass opacities, is more common to have appeared at the late-phase of the disease. Moreover, pulmonary involvement increases with increasing the elapsed time. In total, these findings are consistent with the majority of previous studies [23, 24, 25].

Because it is very crucial to identify the O_2 saturation level at which a patient is needed to undergo a CT-scan test for measuring the severity of pulmonary involvement, we also considered the relationship between O_2 saturation level and the imaging's finding in our study. Our study showed a direct relationship between the severity of pulmonary involvement and decreased oxygen saturation, but this direct relationship was not observed among individuals aged between 20-40 years. This finding is important because it shows that younger patients with almost normal oxygen saturation can have severe pulmonary involvement. According to some studies in literature, patients with oxygen saturation < 93% should undergo imaging procedures [26, 27]. However, we argue this finding, because considering the recommend-dations provided in these works [26,27] may delay the proper treatment and makes the COVID-19 patients more vulnerable to the adverse events of the disease. Therefore, it is proposed that the oxygen saturation level alone is not an exclusive nor a decisive factor to decide on considering a chest CT-scan imaging, and yet patient's overall clinical conditions and all symptoms together should be considered more carefully to decide on offering chest CT-Scan and other diagnostic procedures.

CONCLUSIONS

This study aims to remind doctors involved in COVID-19 diagnosis and treatment around the world to start the treatments immediately and uninterruptedly for patients with chest CT-scan results similar to those highlighted in the present study and several other studies to prevent more losses. We believe that implementing these suggestive CT-scan patterns of COVID-19 patients, can accelerate the proper treatment and prevent more mortality and morbidity.

ORIGINAL ARTICLE

Climate change and public health – past, present, future

Viorel Ordeanu[1,2], Lucia E. Ionescu[1]

Abstract: *The evolution of the planet's climate is multifactorial influenced and has a dynamic over time. Many scientists have approached this controversial field, and each relies on objective but divergent statistics.*

Geographers have established that planet Earth is in a period of slight slow cooling, not at the level of the four prehistoric ice ages, but only at the level of the Little Ice Age from the Middle Ages which probably caused the great migration of peoples from Asia to Europe. This slow cooling is only slowed down and may even be partially reversed by anthropogenic activities. The industry produces large amounts of carbon dioxide from burning fossil fuels and other greenhouse gases. Animals produce carbon dioxide through respiration and digestion, some also methane. The waste degradation, fires, volcanic eruptions, swamps, and thawing of permafrost release carbon dioxide, methane, and other greenhouse gases into the atmosphere.

Climate change exit and has always existed, but there is no scientific evidence for global warming or for climate risks other than those we already know. Public health is already facing danger, directly and indirectly, for multiple reasons, to which „climate change" is added.

Keywords: *global warming, climate change, public health, greenhouse effect, ecology, climate warfare*

INTRODUCTION

Towards the end of the twentieth century, the written and audiovisual media bombarded us with alarmist information about „global warming", but this did not come true. At the beginning of this century, the same media informs us about „climate change", the shortcomings it creates and the risks we will be exposed to. But as American writer and journalist Mark Twain humorously wrote, „If you don't read the newspaper, you're uninformed. If you read the newspaper, you're misinformed"

Is the climate changing?

It is known that the evolution of the climate on the planet is multifactorial influenced and has a dynamic over time, from one geological era to another, from one age to another, from one geographical region to another, from one year to another, according to the season, the circadian cycle and even from one moment to the next. Many scholars have approached this controversial field, some for, some against or simply trying to be impartial. Each relied on objective statistics, those mathematical tools about which the Germans say only half-jokingly: „Statistics is a science that can prove anything, absolutely anything...".

In our country, the geographer Prof. Elena Teodoreanu, who was also a scientific researcher in medical geography, tried to answer this question, systematizing the knowledge in the field in her book entitled „Is the climate changing? A question at the beginning of the millennium" [1]. She stated: „It is strange how a simple look at the climates of the Middle Ages shows us the existence of calamities in past centuries as well – droughts, floods, destructive frosts – and yet, nowadays, a certain state of unrest about climate anomalies, is made felt in almost all countries. It is obvious that the possibilities of information today are far superior to those of the historical past, which allows knowledge in the shortest time, of events of all kinds around the globe and especially of those that attract attention, disturbance, fear."

ionescu.lucia@gmail.com

Other scientists, some of our own, have asked the same question. Thus, the physicist Ştefan Hepites, who founded in 1884 the Romanian Meteorological Institute, published in 1898 the article „Has the climate changed?” in which it is well documented that it has not. Another head of this institution, the meteorologist Nicolae Topor, published in 1967 the article „Is the climate changing?” in which he demonstrates that the climate does not change and concludes that: „what we are commenting on today are aspects of the same climate, which can change only partially in millennia, and only after millions of years.”

CLIMATE WARFARE

The great catastrophes in Earth's history have not caused human casualties, because humans had not yet appeared on the planet. But the small local catastrophes that ensued left millions or even billions of human casualties in total: dead, wounded, sick, and refugees. In addition, man has created a series of anthropic or even artificial catastrophes: wars, revolutions, attacks, collective or mass accidents, changes in the environment, and much more...

At the time, Walter Orr Roberts, president of the American Association for the Advancement of Science, said: „We aim to put the entire globe under constant observation of the weather until 1970 with reasonable expenses. We assume that we will be able to obtain incomparably better forecasts on storms, frosts, droughts, and smog and we will be able to avoid disasters. But behind these advantages that science brings us lies the danger of a potentially terrible weapon of war - the deliberate manipulation of the weather in favor of a small number of people in power, to the detriment of the enemy and perhaps those who stand aside.” [1]. This conclusion does nothing but reminds us of the threats made by the heads of the Great Powers, Stalin and Bush jr., summarized in the expression: „He who is not with us is against us.”

In 2004, the French writer Jouzel Debroise published the book „Climate – a dangerous game”. The following year, the „Final Report, Air University of the US Air Force, AF 2025”, is published, stating: „Climate change will become part of domestic and international security and can be done unilaterally. The ability to generate rain, fog, hurricanes and to change or produce certain weather conditions is part of the same set of technologies that can weaken the opponent and allow access to domination, wealth and power.” [2]

It is estimated that the enemy's combat actions, logistics, and transport may be hampered, food crises may be created to starvation, the outbreak and spread of natural or biological-induced epidemics may be favored, and medical countermeasures may no longer act effectively. It seems that the United States and Russia already have the capacity for climate warfare, and politicians are interfering in climate research. In 2009, General Emil Străinu published the book „Geophysical Warfare. Techniques for modifying the environment for military purposes” [3] which draws attention to the risk following attempts to change the weather and presents some situations of alleged climate attack on some countries, including Romania.

Geophysical warfare, which also includes climate change or climate catastrophes, would also be a major challenge for military medicine and public health in general. New problems of pathology and epidemiology, diagnosis, treatment and prophylaxis, health logistics would appear, specialized forces and means would be needed, and in their absence, the situation could quickly degenerate into a biological crisis.

THE PHENOMENON OF „GLOBAL WARMING”

Although the natural change of the climate is imperceptible and the anthropic change is very discreet, the observation of seemingly frequent catastrophic consequences has launched the hypothesis of global warming, which should be stopped. It seems that initially, the fight against „global warming” was an attempt initiated by the US to slow down the boom of the Chinese R.P. economy, whose energy was based on coal. The Chinese have large deposits of coal, but no oil and gas, which they are currently looking for in the South China Sea. However, in the meantime, China has become the world's second-largest economic power, and the expansion of the fight against carbon dioxide (greenhouse gas) produced by burning fossil fuels (including oil and gas) is also hitting the US economy, largest producer and consumer of energy. As a result, Donald Trump, as US president, no longer supported scientific research on „global warming” and the United States withdrew from international organizations that oppose this controversial phenomenon. But at the same time, NASA publishes alarming studies showing that global warming tends to become irreversible, with serious consequences, including Arctic ice melting, rising sea levels, and flooding areas, with the cities of London, New York, Sydney, etc. [4]. The areas populated by „natives” did not get the attention of these world science leaders.

If we think about the planet's distant past, the atmosphere was much different: more oxygen, much more carbon dioxide than now, excess water vapor and heat, all in one place favoring the giant Carboniferous plants and the giant Jurassic animals. But even today the richest fauna and microfauna, as well as the richest flora and microflora are found in the equatorial jungles. So we can think that the danger is not so much for the thriving biosphere as for the business world that will have to adapt to the new conditions.

Due to the lack of scientific evidence on global warming (it can neither be clearly shown that it exists nor that it does not) another paradigm has been used: climate change. For now, specialists in the field are reluctant and do not express firm opinions, whatever is possible, in the near or distant future.

WHAT IS REALLY HAPPENING?

Geographers have established that planet Earth is in a period of slight slow cooling, not at the level of the four prehistoric ice ages, but only at the level of the Little Ice Age from the Middle Ages (when, in one winter, the Nile froze) which probably caused the great migration of peoples from Asia to Europe. This slow cooling is only slowed down and may even be partially reversed by anthropogenic activities. The industry produces large amounts of carbon dioxide from burning fossil fuels, as well as other greenhouse gases. Animals produce carbon dioxide through respiration and digestion, some also methane. The waste degradation, fires, volcanic eruptions, swamps, and thawing of permafrost release carbon dioxide, methane, and other greenhouse gases into the atmosphere. All this contributes to slight heating, especially in the most industrialized or zoo-intensive areas.

Meteorologists' measurements are very accurate, their thermometers measure air and water temperatures by tenths of a degree Celsius, and the records and reports are very rigorous, at least in recent centuries. But the place of measurement, the location of the weather station, remained in place although the anthropic area (housing and industry) is constantly expanding and warming the environment. As an example, the first Romanian weather station was in Bucharest, on Filaret Hill, where the Astronomical Observatory was located. As the area became more and more populated, and the station was now in the city, a second weather station was set up, in Băneasa, outside the city, in the North-West direction, where the predominant wind comes from. So the weather in the city could be compared with the weather outside the city. In the beginning, the recorded temperature differences were about 2°C, but now they are on average about approx. 1°C, due to the expansion of urbanization in this area as well. Almost all weather stations are currently included in urban areas, so they report very accurately measured temperatures, but with systematic error in addition to the respective geographical area, an involuntary falsehood.

For some, the mild winters of recent years, through early February, would be evidence of „global warming”. But I could give some examples from personal memories: after the winter of 1971-1972, when the Black Sea froze on the shore and seaports including Mangalia were blocked (river ports are the ones blocked every year), the old sailors said they had never seen anything like it since they were young. But in the winter of 1973-1974, it was spring-like weather; on February 11th (my birthday) I went for a walk along the seafront wearing just a suit. And ten years ago, when my niece was born, on February 9th, 2009, I went to the maternity ward in a suit, in spring-like weather. But that hasn't stopped the Black Sea from freezing again in 2011 as well as in other, more recent years. All this means that the climate is neither heating nor cooling, but that it is only a random variation between certain limits, a statistical dynamic with a sawtooth pattern. And the slightly ascending „regression line” could just be the result of the systematic error I pointed out before, or it could be the „sawtooth” pattern of statistics applied to another time scale.

ASSUMPTIONS AND EVIDENCE

Many see as objective evidence the partial melting of mountain glaciers and polar caps, especially in the Arctic, and the rising of the worldwide ocean levels. Anyways, every summer the polar caps fragment on the edges and partially melt, and during the polar winter they grow back. The phenomenon is so repeatable that nautical charts mark the minimum and maximum limits of the polar ice caps. If the alarm is real, major potential hazards arise from this. If the mountain glaciers would melt completely (the most important being in the Himalayas), the rivers and streams in Asia will no longer be supplied with water and there will be a shortage of freshwater, which will affect billions of people. This phenomenon could lead to water wars involving billions of people.

If the polar caps melt in time, the level of the Planetary Ocean will increase by approx. 10 m due to the Arctic and approx. 80 m because of Antarctica. [5]. It is believed that if all the solidified water on the planet melted, the sea level could reach almost +100 m isobaths, and the land area would be reduced by about a third. The land surface will be reduced from almost 30% to less than 20% of the globe's surface. But these major changes, which would take thousands of years, are hypothetical, just some apocalyptic scenarios imagined by some journalists (who want the public's attention) and some politicians (who want to show that their country could save the planet) or by others as such, which are not seriously taken by scientists.

For now, we see that the partial melting of the Arctic polar cap allows ships from the far North to move, during the boreal summer, on the Arctic Ocean (Northern Frozen Ocean), both through the East Passage, between the Atlantic to the West and the Pacific to the East north of Europe and Asia, as well as through the Western Passage, between the Pacific to the West and the Atlantic to the East (North of Canada). These new sea routes shorten freight routes and favor the great maritime powers (USA, Russia, China, etc.). Unfortunately, Romania, which was the 11th maritime power in the world Knowledge Horizons – Economics, no longer has many ships, so it will not be able to benefit from this opportunity [6].

The thawing in Northern Canada, Greenland, and Siberia also facilitates mining, oil, gas, etc., thus favoring economic development. But this is where the serious problem arises. The thawing of the Siberian permafrost (swamps frozen for thousands of years or still frozen since the last glaciation) allows the slow emanation of methane in the soil (natural biogas) and it has a greenhouse effect [7]. The complex industrial pollution in the area of the North Polar Circle, in continuous development, reduces the snow's albedo, which instead of reflecting most of the solar radiation, absorbs it and melts rapidly.

At present, this phenomenon may be intentionally potentiated by humans. The US military's High-Frequency Active Auroral Research Program (HAARP) aims to bombard the ionosphere with strong radio waves, heat it, and reflect it to the ground, causing heat and devastating phenomena. If this biophysical weapon becomes operational, it may also be used for peaceful purposes, for the benefit of the Arctic industry but aggravating the phenomenon of melting ice. It may not be a coincidence that specific US facilities are located in Alaska, Greenland, and Norway, and the Russian ones in Siberia [8, 9].

At the same time, it is observed that on the contrary, the Antarctic cap is not reduced there is an increase in area and thickness. And the Great Powers are already disputing the division of Antarctica to begin mining for minerals under the ice cap. Political, economic, financial, and military forces, state and supranational, as well as large multinationals, are repositioning themselves for the new negotiations on the Law of the Sea, the polar caps, and the outer space. The multipolar world is complex, unpredictable, and dangerous, especially for the little ones. As the poet Gr. Alexandrescu said: „We want equality, but not for puppies".

PUBLIC HEALTH CONSEQUENCES

Overall, the prosperity of a nation and its bio-psycho-social health are climate-dependent. The World Health Organization has defined the concept of human health as „physical, mental, intellectual and social well-being", or all these are interdependent and multifactorial conditioned. Holistically speaking, everything around us and everything that happens to us is reflected, directly or indirectly, in public health, in the broadest sense [10].

It is considered that it would be possible that if the average temperature increased by 4°C, the level of the Planetary Ocean would increase by 9 m. The areas with the largest population and the most developed economy would be flooded; all beaches, all low plains, all ocean and sea ports, most islands, and even entire countries such as the Netherlands, Bangladesh, and others would disappear. This hypothetical global catastrophe would lead to a population exodus of billions of people, with poverty, epidemics, and wars [11]. In our country, too, major changes would occur: the Romanian coast, as we know it, would disappear and return to its former form, the Danube Delta will once again be a bay of the Black Sea, and the Danube would flow into the sea through a long estuary from Calarasi to Galati, and northern Dobrogea could be an island or a peninsula. In this unlikely situation, the land area of Romania would be reduced to only approx. 200,000 km2 but the water area would increase [12].

If this global catastrophe were to occur in the coming centuries, the consequences for public health would be particularly serious for all states and all nations. It is already believed that climate change, with warming in some regions, such as Europe, favors the emergence of exotic and tropical diseases, which although at the beginning, only „import diseases", will spread and could become endemic diseases or epidemics in the temperate zone, so in populations that do not have natural protection against new pathogens. This creates a pandemic potential for exotic and tropical infectious diseases. Examples can be found permanently in the epidemiological communiqués of the World Health Organization (WHO), Center for Diseases Control, USA (CDC), European Center for Disease Control (ECDC), Ministries of Health (MoH), etc. and we will not insist on them. We know and sometimes we even face these diseases. But we will have to reconsider the entire public health monitoring system to deal, at least conceptually, with any present or future situation [13].

It should also be mentioned that if our Roman ancestors were afraid of the heat (heat wave – dog weather), we Romanians are afraid of the cold (dog weather), and jokers say that our Dacian ancestors, "the bravest of the Thracians", were not afraid of anything, only of draught and that's why they walked around wearing little hats covering their ears both in winter and during summer. Anyway, the

Romanian expressions “to stay warm”, “tucked up nice and warm”, and “someplace warm” express the preferences of Romanians, unlike those of Americans for whom being “cool” is a good thing. Let's not forget that the Romanian greeting formula “salut” comes from the Latin greeting of health (salus), which, as the Romanian people say, "there is nothing more important than good health". And the Romanian rulers used to welcome their equals and subjects with the greeting: "May all those present be healthy!" a wish that we also address to our readers. The international importance of climatic change for public health shows over 35 000 scientific articles indexed on the Web of Science [14].

A very special issue in this context, and which can become a global threat to humanity, is posed by biological agents of war and those of bioterrorism. Biological warfare was formally banned, meaning „with proper documents”. But this is only a formality. The Convention on the Prohibition of Biological Weapons, launched by the United Nations (UN) in Geneva (BTWC 1972) follows other conventions that prohibited, implicitly or explicitly, the use of biological weapons. But there are still no real control mechanisms and biological agents have been used repeatedly for biological attacks. The convention was accepted by approx. 90% of the countries of the world (including all the states of the European Union), which seems to be a very good situation. But the remaining 10%, who have not signed or ratified the Convention, represent about 20 states with about a quarter of the world's population [15].

Moreover, the Great Powers do not allow international control over their territory or military bases. On the contrary, Iraq, which had biological weapons but also destroyed them, was accused of possessing biological weapons, was attacked and invaded, almost destroyed, but no biological weapons were confirmed. The foreign invasion troops (peacemaking) were replaced by occupation troops (peacekeeping) and did not leave completely even after 17 years. Currently, Iraq is considered by the international community as one of the "failed states" but no guilt has been established so far and the "international community" and "public opinion" have not been effectively involved in resolving this critical situation.

Biological warfare agents (BWA) are living microorganisms (bacteria and viruses) and toxins obtained from living organisms, which are disseminated with the help of biological weapons: aircraft or spray aerosolization, explosive munitions such as missiles, air bombs, and artillery shells, or diversionary agents. In a broad sense, the disease itself, usually infectious-contagious and/or zooanthroponotic caused by biological agents is considered a biological weapon. Officially, 7 bacterial species, 3 groups of viruses, and 5 toxins are listed. This list is exhaustive due to the characteristics required for effective military use. In contrast, bioterrorists can also use any other pathogens for humans, animals, and/or plants (bacteria, viruses, prions, fungi, parasites, etc.) to make people sick, reduce agricultural or animal production, to create food crises. It should be noted that biological warfare viruses are not listed as species, but only as groups, which means that in hemorrhagic fevers, for example, Ebola, Marburg, and many more are implicitly included. This will technically (not legally) allow the use of exotic and tropical viruses in areas affected by global warming and explain the medical-military interest of some states for medical intervention in these epidemics [16].

THE NEW EUROPEAN UNION POLICY FOR ENVIRONMENTAL PROTECTION

The current President of the European Commission (EC), a kind of Prime Minister of the Government of the European Union (EU), and the former German Minister of Defense (Bundeswehr), Ursula von der Leyen, is a doctor by profession. In 2019, at the moment of her election, she published the document “A Union that strives for more. My agenda for Europe” in which she stated that “for the generation of my children, Europe is the only aspiration” [17]. Of the six priority goals she has proposed for the next 5 years, the first is A European Green Deal (an ecological Europe) and she said “I want Europe to strive for more by being the first climate-neutral continent”, partly by 2030 and partly by 2050. This requires investment in innovation and research, redesigning the economy, updating industrial policy, and a new industrial strategy. Some complied and immediately found a "minimum method" of application, without investment: they take some extra money from drivers and other small polluters, and that's about all for now [18].

But the new ecological conception was already rooted in the world for many years. We pay more for electricity because we also use more expensive, unprofitable, but environmentally friendly technologies. Electric cars are in vogue, since 1905 exceeded the speed of 100 km/h, but they were not imposed for technical and cost reasons, but there are fears that they will become mandatory. For the emotional awareness of the public opinion, at the end of 2019, an ecological skit was broadcast, in which the filmmakers did not shy away from using an autistic teenager. Was that politically correct? And maybe some were wondering, „What's next?” This was followed on February 1st, 2020 by the World Economic Forum (WEF) in Davos (Switzerland), with the main theme of the year:

„Stakeholders for a Cohesive and Sustainable World” (united shareholders for a sustainable and cohesive world), under the slogan „How to Save the Planet”. 3,000 delegates from the largest private companies participated. Work has been conducted to prepare for the massive reorientation of global capital flows, through which financial giants, including the World Bank and the European Central Bank, are repositioning themselves to maximize their profits. As an example, only the promoter of this initiative, the BlackRock investment fund, has to invest over 7 trillion dollars (i.e. thousands of billions), more than the annual budget of most countries. The Davos Forum has been strongly involved in the Climate Change Agenda. Although it is acknowledged that it is impossible to answer the question: „when will climate risk have an impact on the planet's economy?”. It is considered that climate risk is also a risk for investments and that there will be a massive reallocation of capital through the Green Finance Initiative. Thousands of billions of dollars of investment funds will be channeled to „green” projects, so funding is not for everything and especially not for everyone. But in the meantime, the outbreak of the Covid-19 pandemic partially canceled the old plans, replacing them with the Great Reset of the world economy for the benefit of the Great Powers, the world's great finances, and multinationals. The US has an ambivalent position [19].

It seems that the „climate change” paradigm will be imposed to become the „new religion” of the 21st century, with a God whom, although we do not perceive, His priests are threatening us in His name. There is a risk that money, not work, will become the engine of progress and well-being, including the source of public health. But the investment will be directed at „rule of law” states that stand upright in the face of great global finance. However, we have the advantage that we are members of the European Union, we shall rise with it and, God forbid, we will fall with it [20].

In 2019 the „international community” says that the present situation is a „climate emergency” and in 2020 Roumanian Academy publish a „point of view” about climate change [21].

CONCLUSIONS

Climate change exists and has always existed, but there is no scientific evidence for global warming or for climate risks other than those we already know. But we find them better and faster, and the damage is greater because the population is larger and the human environment is more extensive, including in risk areas. Public health is already facing danger, directly and indirectly, for multiple reasons, to which "climate change" is added. It seems that the problem is mainly political, with economic and financial implications, and will be used as financial leverage at the global level, for global interests. For now, let's remain optimistic, but also prepared and vigilant.

CLINICAL PRACTICE

Clinical and dermatoscopical aspects of pigmented basal cell carcinoma – Case series and literature review

Anton M. Țilea[1], Viorel Trifu[1], Bogdan Dima[2], Mihai A. Badea[3], Raluca S. Costache[1], Daniel O. Costache[1], George S. Țiplica[4]

Abstract: *The diagnosis of pigmented basal cell carcinoma can bring significant distress to patients and physicians alike. However, astute clinicians that can employ correctly the clinical and dermatoscopical clues can reach a correct preoperative diagnosis, and as such can avoid unnecessary worry for the patient, additional work-up, or overtreatment. We present a case series of pigmented basal cell carcinomas and a comparative case with pigmented cutaneous melanoma, together with a literature review, that will highlight these aspects of the management of pigmented tumours of the skin.*

Keywords: *dermoscopy, basal cell carcinoma*

INTRODUCTION

Pigmented tumours of the skin bring significant distress to patients and to physicians alike. While pigmented basal cell carcinoma is not a benign tumour, its prognosis is highly favourable if it is diagnosed and treated early. The dermatologist is also in the position to tell the patient that even if the tumour to be excised is a malignant tumour, the treatment, i.e the excision of the tumour, will result in the complete healing of the lesion, with a low probability of local recurrence.

We present a case series of pigmented basal cell carcinomas and a review of the literature in an effort to show that this particular pigmented tumour of the skin can be easily identified by the experienced dermatologist with the aid of clinical and dermatoscopical clues.

REVIEW OF LITERATURE

Background

One of the oldest references [1] to pigmented basal cell carcinoma (pBCC) in PubMed involves a differential diagnosis with cutaneous melanoma. Indeed, the spectrum of pigmented cutaneous melanoma (PCM) can plague the management of a pigmented lesion of the skin leading to overtreatment, if a wide excision of the supposed PCM is intended, and/or to unnecessary worry of the patient and extended additional work-up, e.g. lymph-node ultra-sonography, lung radioscopy etc.

Goldenberg et al [15] describe the age-adjusted incidence of BCC in American population to be 226 per 100000 persons and the age-adjusted prevalence of BCC to be 342 per 100000 persons.

Maloney et al [13] and Betti et al [14] describe the histopathology epidemiology of pBCC to be of around 6.7% and 8.5% respectively of the total cases of BCC taken into consideration.

Altamura et al [17] found that actually the dermatoscopically non-pigmented BCCs can be as low as 15.1%, and the rest of the BCCs have some degree of pigmentation, from low to heavy. They [17] have not used the diagnosis of pBCC according to the histopathology, but according to the dematoscopical features pigmentation, albeit all lesions were confirmed with histopathology to be BCC.

Both studies, of Maloney et al [13] and Betti et al [14] found that pBCC has a better prognosis with clear excision margins than the other types of BCC. A similar conclusion is reached also by Ito T et al [6] by saying that narrow-margins excision of 3mm may be enough to obtain clear margins for pBCC, as opposed to 4mm margins required for classic non-pigmented BCC.

Clinical aspect

The clinical aspect of BCC should not be disregarded as we consider that an astute clinician can observe significant clinical clues that can lead him to an appropriate preoperative diagnosis.

Bolognia et al [11] describe the clinical aspect of a nodular BCC as “shiny, pearly papule with a smooth surface and the presence of arborizing telangiectasias”. They [11] also describe a “thin rolled border” in superficial BCC.

Wu et al [12] describe the clinical aspect of BCC to have a “pearly or translucent quality” with telangiectasias, the lesions having a “periphery more raised than the middle” – a rolled border. In addition, they [12] say that “a shiny quality” can be observed when a superficial BCC is illuminated.

Huang et al [10] used translucency as a clinical indicator to learn computer aided systems to detect BCC and achieved a 93% accuracy.

Dermatoscopy

Dermatoscopy, if correctly employed, can be an invaluable tool in diagnosing BCC and especially pBCC.

A very thorough article on the dermatoscopy of pBCC is the one of Menzies et al [5]. They established that there are several highly specific dermatoscopical patterns, e.g. “maple leaflike areas” and “spoke wheel areas” that have a specificity of 100%, albeit a low sensitivity of 17% and respectively 10% [5, 16]. Other dermatoscopical criteria with high specificity were “large grey-blue ovoid nests”, “multiple grey-blue globules” and “arborizing (treelike) telangiectasia” [5 , 16].

Marghoob et al [7] also describe several specific dermatoscopy aspects for pBCC: large blue-grey ovoid nests, multiple blue-grey globules, leaf-like structures, spoke-wheel-like structures, arborizing telangiectasias and ulceration.

Kittler et al [8] describe the dermatoscopic patterns of pBCC as “radial lines, dots, clods and structureless zones” and they say that a common pattern is blue clods of different shapes and sizes. In addition, other structures may appear, such as brown clods, grey, blue and brown dots, white structureless zones and radial lines. They [8] also describe patterns that are very strong indicators against BCC, e.g. non-radial lines (reticular, branched, curved and parallel), pseudopods and circles. Also, the description of the typical vessels found in BCC would be: “branched serpentine vessels that originate from thick stem” – usually found in nodular BCC, while in superficial BCC a polymorphous pattern of vessel can appear, e.g. thin, serpentine and coiled vessels. The pattern of dot vessels is a strong indicator against BCC [8], unless found within ulceration.

Cabo et al [9] considers the dermatoscopical pigmented structures, e.g. maple leaflike areas, spoke-wheel area, multiple blue-grey dots or small globules, blue-grey ovoid nests to be characteristic for pBCC, while “white shiny blotches and strands” are an additional criterion only seen with polarized dermatoscopy.

Felder et al [18] and Turkmen et al [19] describe a dermatoscopical blue-white variant of pBCC. This type of pBCC is included in the class of heavily pigmented BCC as described by Altamura et al [17]

Lallas et al [21] describe dermatoscopic features to differentiate between superficial BCC (e.g. maple-leaf like areas and short, fine telangiectasias) and nodular BCC (e.g. blue-grey ovoid nests, arborizing vessels, ulceration). Wozniak - Rito et al [20] agree with these findings.

Additional work-up

Usually additional work-up is not necessary for the diagnosis of pBCC. However, cytology i.e fine needle biopsy can be used [3] in certain cases that the clinical and dermoscopical aspects are not enough to establish a certain diagnosis. Usually this happens when the lesions are pure nodular, without a superficial part.

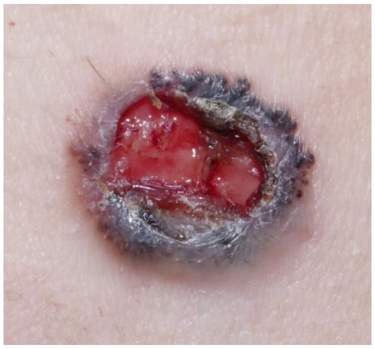
CASE SERIES

Case 1

A 59 years old female patient presented to our dermatology department for a 2/2 cm, ulcerated, pigmented lesion in the left axilla. The lesion had a history of about 8 years. The patient also had a personal history with another BCC lesion operated 10 years prior to this admission.

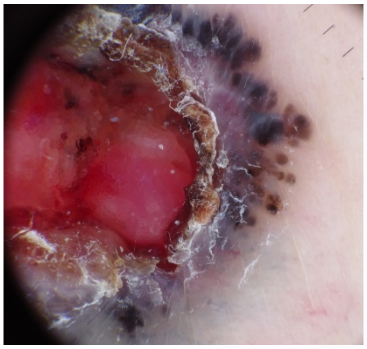
The clinical aspect of the lesion (Figure 1):
- central ulceration with serohematic crust on the surface,
- the non-ulcerated part of the lesion has a translucent greyish feature with superimposed dark-brown, blue, black punctate pigmentation
- the periphery of the lesion has a pearly pigmented aspect
- the lesion has a smooth-shiny surface that does not continue the adjacent normal skin architecture

Figure 1: The clinical aspect of Case 1 has a very specific pearly-pigmented aspect of the periphery of the lesion along with a translucent quality



The dermatoscopical aspect of the lesion Figure 2:
- brown and blue-black-grey ovoid nests
- leaf-like areas (high specificity for pBCC)
- fine telangiectasias
- ulceration

Figure 2: The dermatoscopical aspect of Case 1 has leaf-like areas and brown and blue-black-grey ovoid nests

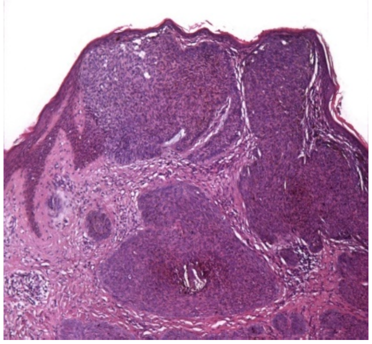


The lesion was excised with 4 mm margins and the histopathological examination established the diagnosis of pBCC, (Figure 3) with islands of basaloid cells with peripheral palisading, clefts between the islands and the stroma, and focal deposits of melanin within the basaloid islands.

Case 2

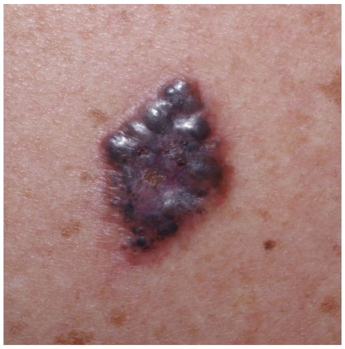
A 63 years old male patient presented to our dermatology department for a 1.5/2cm pigmented lesion on the posterior thorax. The lesion had a history of about 1 year. The patient had no significant medical history.

Figure 3: The histopathology of Case 1 established the diagnosis of pigmented basal cell carcinoma



The clinical aspect of the lesion (Figure 4):
- small central ulceration
- translucent feature of almost the entire lesion with pigmentation – large pearly structures pigmented bluish-black
- shiny smooth surface that does not continue the architecture of the adjacent normal skin

Figure 4: The clinical aspect of Case 2 has an overall pigmented pearly and translucent feature with shiny smooth surface



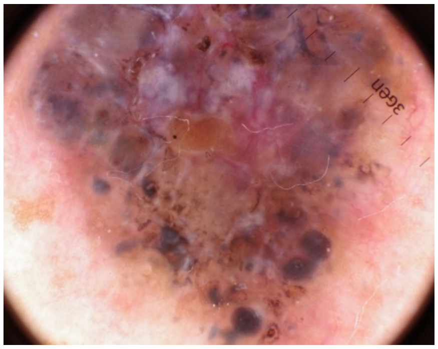
The dermatoscopical aspect of the lesion (Figure 5):
- blue-grey ovoid nests and globules
- arborizing telangiectasias
- the polarized dermatoscopy image showed white lines and blotches

The lesion was excised with 4mm margins and the histopathological diagnosis confirmed it was a pBCC.

Case 3

An 82 years old female patient, with no significant medical history, presented to our dermatology department for a 0.7/0.7 cm pigmented lesion on the left thigh. The lesion had a history of about 6 months.

Figure 5: The dermatoscopical aspect (polarized) of Case 2 has blue-grey ovoid nests, arborizing telangiectasias and white lines and blotches



The clinical aspect of the lesion (Figure 6:

- central ulceration with serohematic crust on the surface
- translucent aspect the lesion with a general violaceous – bluish aspect and some brown pigmentation on the periphery of the lesion
- shiny smooth surface that disrupts the normal adjacent skin architecture (Figure 7)

Figure 6: The clinical aspect of Case 3 has a translucent violaceous-bluish aspect and a shiny smooth surface

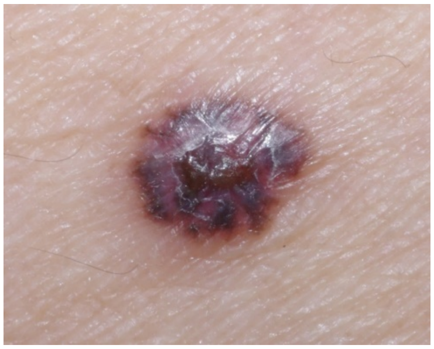


Figure 7: The particular aspect of shiny smooth surface that disrupts the normal adjacent skin architecture

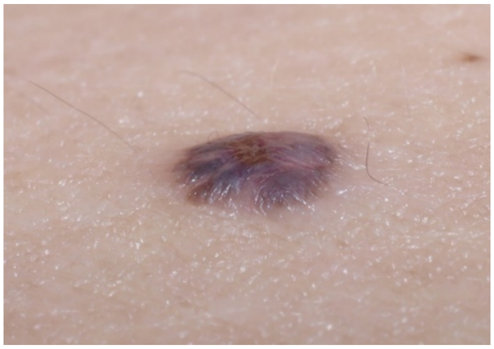
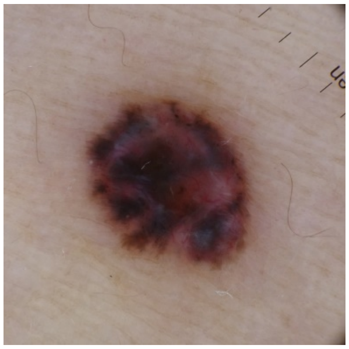


The dermatoscopical aspect of the lesion (Figure 8):

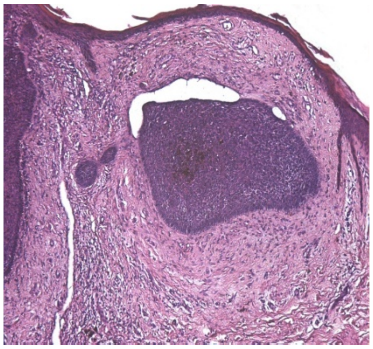
- blue-grey ovoid nests
- arborizing telangiectasias
- leaf-like structures (within the brownish periphery pigmentation)
- ulceration
- white lines and blotches (observed with polarized dermatoscopy)

Figure 8: The dermatoscopical aspect (polarized) of Case 3 has leaf-like areas and blue-black ovoid nests, arborizing telangiectasias and white lines and blotches



The histopathology of this lesion (Figure 9) confirmed the clinical and dermatoscopical diagnosis of pBCC, observing islands of basaloid cells with peripheral palisading, clefts between the islands and the stroma as well as deposits of melanin within the basaloid islands.

Figure 9: The histopathology of Case 3 observed islands of basaloid cells with peripheral palisading, clefts between the islands and the stroma, deposits of melanin within the basaloid islands reaching the diagnosis of pigmented basal cell carcinoma



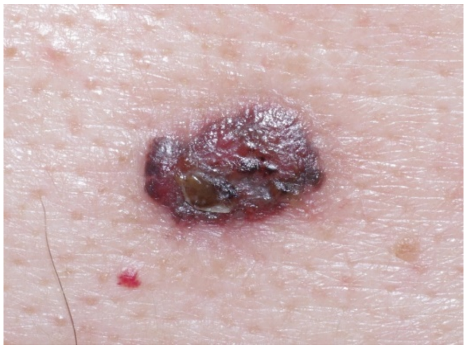
Case 4 – Comparative case

As our fourth case we present a lesion that highly resembles the clinical appearance of the Case 3 lesion (Figure 6), however the dermatoscopical aspect of this lesion has a rather conspicuous lack of clues for any specific diagnosis.

A 66 years old male patient, with no significant medical history, presented to our dermatology department for a 0.7/1.4 cm pigmented lesion on the abdomen. The lesion had a history of about 6 months.

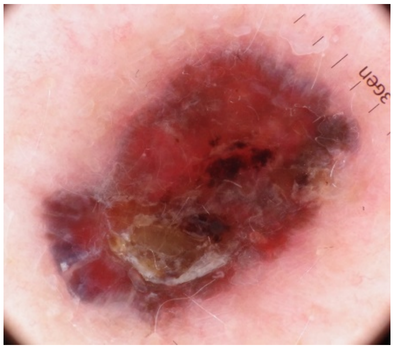
The clinical aspect of the lesion (Figure 10):
- ulceration with serohematic crust
- pigmentation – pink – red – violaceous – black
- textured surface – tends to keep the architecture of adjacent normal skin, even if somewhat disorganized (the surface is not smooth - shiny)
- ovoid/rather rectangular shape

Figure 10: The clinical aspect of Case 4 observed rather similar type of pigmentation with Case 3, i.e. pink – red – violaceous – black, however with a textured surface (as opposed to Case 3, here the surface is not shiny)



The dermatoscopical aspect of the lesion (Figure 11):
- ulceration
- pink – red – violaceous colour
- white lines and blotches on the periphery of the lesion (polarized dermatoscopy)
- lack of specific clues for pBCC (blue –grey ovoid nests, leaf-like structures, arborizing telangiectasias)

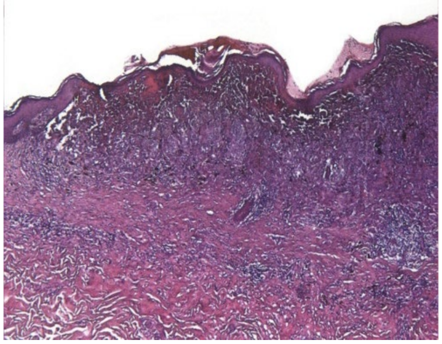
Figue 11: The dermatoscopical aspect of Case 4 has pink – red violaceous colour with lack of specific clues for pBCC



The histopathology of this lesion (Figure 12) reached the diagnosis of pigmented cutaneous melanoma (PCM), with a Breslow thickness of 0.8 mm.

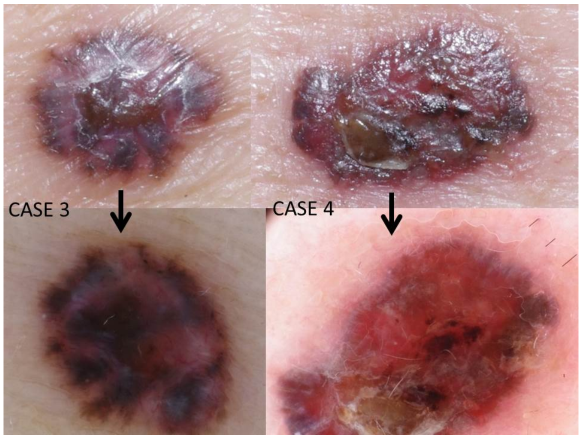
As a discussion of Case 3 vs Case 4, Figure 13 presents a comparative view of both the clinical and dermatoscopical aspects of both lesions. On the clinical part, both lesions are ulcerated and have somewhat the same type of pigmentation.

Figure 12: The histopathology of Case 4 established the diagnosis of pigmented cutaneous melanoma, Breslow thickness of 0.8 mm, Clark IV



However the clinical clue of smooth – shiny surface that disrupts the normal adjacent skin architecture can be found in Case 3 and not in Case 4 where we find a textured surface of the lesion that tends to keep the normal adjacent skin architecture, even if somewhat disorganized. On the dermatoscopical part, both lesions present ulceration and similar type of pigmentation. However, while the Case 3 dermatoscopy image has conspicuous clues for pBCC, Case 4 dermatoscopy has a discomforting lack of clues for pBCC or for other pigmented lesion of the skin. Even though the polarized dermatoscopy clue of white lines and blotches are present in both Case 3 and Case 4, this comparative case shows that this particular clue cannot be used to differentiate between pBCC and PCM.

Figure 13: Comparative view of clinical and dermatoscopical aspects of Case 3 and Case 4



DISCUSSIONS

Regarding the epidemiology of pBCC we think that if the clinical and dermatoscopical aspect of pigmented structures within a BCC lesion are taken into consideration when establishing the pBCC diagnosis, the percentage may be significantly higher than what the studies of Maloney et al [13] and Betti et al [14] are suggesting, 6.7% to 8.5% . This may be because even in clinically non-pigmented BCC, the dermoscopy may reveal some pigmentation [17, 22], e.g. leaf-like structures, blue-grey ovoid nests or globules, and these structures may not appear in a given histopathology slide. To prove our point, Altamura et al [17] found that some degree of dermatoscopical pigmentation could be found in almost 85% of the BCC lesions. Therefore, the quantitative feature of the pigmentation may have an important role to play in reaching a histopathological diagnosis of pBCC.

To our knowledge, the clinical clue of disruption of the adjacent normal skin architecture within the lesion of a superficial pBCC has not been clearly described so far. There are papers that describe the “shiny quality” [12] or “shiny… smooth surface” [11] in superficial BCC and we think it refers to the same clinical quality. We consider this clinical clue important because superficial spreading cutaneous melanoma tends to conserve adjacent normal skin architecture within the lesion, as opposed to pBCC.

The clinical clue of pigmentation, even though is the most worrisome in the differential diagnosis of pBCC with PCM, should be observed within the overall aspect of the lesion, e.g. pearly translucent feature, rolled border.

If the clinical aspect of a suspected pBCC lesion is not enough to reach a correct diagnosis, usually dermatoscopy comes with supplementary clues. Moreover, some clues are highly specific for pBCC, e.g. leaf-like structures and spoke-wheel like structures [5] [7] [9]. Other clues that are indicative for pBCC are blue-grey ovoid nests, globules and dots, arborizing telangiectasias [5] [7] [9] (brown clods, grey, blue and brown dots, branched serpentine vessels that originate from thick stem [8]).

Even though the clinical and dermoscopical aspects of the pBCC are usually enough to diagnose a pBCC, there are papers [2 -4] that do not use dermoscopy as an aid.

On the other hand, papers focusing on dermatoscopy tend to overlook the clinical aspect of the lesion. As such, Turkmen et al [19], even though they present the clinical aspect of the lesions, the pictures are small and cannot be evaluated properly. In their article [19] the Case 3 and Case 6 seem to have a rolled border that may be a strong indicator for BCC, considering the fact that the dermatoscopical aspect, with blue-white veil cannot differentiate between pBCC and pigmented cutaneous melanoma (PCM).

While we consider the dermatoscopical aspect of pBCC of paramount importance, considering the highly specific clues that can simply establish the diagnosis of pBCC, we also consider the clinical clues very important, especially when the dermatoscopical clues are lacking, as we showed in our case series.

Considering the data regarding the clearing of margins in the pBCC management [6] [13] [14] we think that a careful evaluation, clinical and dermatoscopical, of a pigmented lesion can avoid unnecessary worry for the patient, additional work-up and overtreatment.

CONCLUSION

We consider that the clinical and dermatoscopical aspects, as well as the histopathological diagnosis should have a synergy within the management of pBCC.

Therefore, the clinical aspect of pearly border, translucency, and shiny surface – disruption of the adjacent normal skin architecture should be combined with the dermatoscopical aspect of “leaflike areas”, “spokewheel areas”, blue-grey ovoid nests and globules as well as arborizing telangiectasias and the diagnosis of pBCC can be reached in a swift manner. By doing so one can avoid unnecessary patient worry and additional work-up as well as one can adapt the treatment according to the diagnosis. Nevertheless, a biopsy should always confirm the clinical/dermatoscopical diagnosis.

VARIA

Clinical and therapeutic particularities of acute gallstones disease during COVID-19 pandemic

Simona Balasescu[1], Andra Maria Trotea[1,2], Dragos Margaritescu[3], Alexandru Sabau[4]

Abstract: *Gallstones disease (GD) is a common pathology, with an incidence of approx. 20% in developed countries, a third of these cases being symptomatic. The paper aims to identify the diagnostic and therapeutic features of acute manifestations of gallstones during the COVID-19 pandemic.*

Materials and method: A retrospective, comparative study was performed of the cases presented to the emergency room (ER) and hospitalized for acute manifestations of gallstones in April-June 2020 vs similar period of 2019. The data regarding clinical form, associated pathology, therapeutic management were analyzed from the ER presentation register, hospitalization sheets and surgical protocols.

Results: During the COVID-19 pandemic, the number of hospitalized cases for acute cholecystitis and other acute manifestations of GD was significantly lower than in the same period last year (21 vs 49 patients). In both study groups the main form of presentation was acute catarrhal cholecystitis (52.4% vs 63.2%). During the SARS-Cov-2 pandemic, we report an increased incidence of complicated forms, mainly hydrops (23.8% vs. 4.1%, $p < 0.05$) and angiocholitis (19% vs. 4.1%, $p < 0.05$). Conservative treatment was chosen more frequently during the pandemic (48% vs. 29%). For operated patients, laparoscopic cholecystectomy was the main option, performed in 85.7% in both groups.

Conclusions: We maintain that laparoscopic cholecystectomy remains the gold standard for acute cholecystitis, even in the COVID-19 pandemic, as it guarantees the best outcomes for the patients. Conservative management may be an option for mild cases, but it carries the risk of recurrence of symptoms and increased incidence of severe complications.

Keywords: *laparoscopic cholecystectomy, gallstones disease, COVID-19 pandemic, acute cholecystitis*

INTRODUCTION

Gallstones disease (GD) is a common pathology, with an incidence of approx. 20% in developed countries, a third of these cases being symptomatic [1].

Laparoscopic cholecystectomy is the gold standard of treatment for this condition. Acute forms are of clinically variable severity, from possible regressive under conservative treatment to life-threatening, namely: biliary colic, acute cholecystitis, cholecysto-pancreatitis and acute angiocholitis. Early surgical treatment was recommended as

standard in acute cholecystitis to prevent subsequent recurrent episodes, as well as migratory and infectious complications related to the displacement of stones in the main bile duct [2, 3].

The global spread of SARS-CoV-2 pandemic, with the declaration of a state of emergency in our country on the 16th of March 2020, for 60 days, followed by the state of alert since 15th of May, still in force today, had a profound impact on the surgical practice. The initial recommendations of the International and National Surgical Societies were to delay elective surgery, and to attempt first-hand a conservative management of mild and moderate forms presented to the emergency room. Another aspect was that of the aerosolization potential in laparoscopic interventions associated with the induction and dessuflation of the pneumoperitoneum, trocar leakage and laparoscopic smoke. Since the time of SARS-CoV, in 2003, there has been convincing evidence that aerosol-generating procedures (AGP) could potentially result in a wider human-to-human coronavirus transmission radius [4]. Bioaerosols range in size from 0.3 to 100 µm, and particles up to 5 µm remain airborne and can travel distances of more than 100 m, which may be a transmission path for SARS-CoV-2 [5]. Safety guidelines have been developed in laparoscopic surgery to prevent infection of medical personnel in patients suspected or infected with SARS-Cov2, which focuses on preoperative testing of patients, wearing appropriate PPE, consisting of FFP2 masks, goggles or faceshields, ultrafiltration of pneumoperitoneum and preventing accidental leakage of CO2 and plume during laparoscopic surgery [6-13]. Also, the addressability of the population and the desire for surgical treatment was lower for this pathology, partly explained by the fear of a possible contamination in the emergency room or hospital.

Aim

The paper aims to identify the diagnostic and therapeutic features of acute manifestations of gallstones during the COVID-19 pandemic.

MATERIALS AND METHODS

A retrospective, comparative study was performed of the cases presented to the guard room and hospitalized in emergency for acute manifestations of gallstones in April-June 2020 vs similar period of 2019. The data from the presentation register at the guard, hospitalization sheets and surgical protocols, on the particularities related to the clinical form at hospitalization, associated pathology, therapeutic management of patients with acute gallbladder disease, in the absence and during the SARS-CoV-2 pandemic. Changes in the surgical practice of patients with acute manifestations of gallstone disease imposed by international and national guidelines were also analyzed, as well as organizational changes in institutional circuits to prevent the spread of SARS-CoV-2 infection.

RESULTS

Establishing separate circuits within the department for the prevention of SARS-CoV-2 infection

During the pandemic COVID-19, our hospital, an emergency university center with many specializations, made sustained efforts to remain COVID-free, to be able to ensure the safe treatment of patients, and to prevent nosocomial contamination with SARS-Cov2.

In this regard, a strict protocol was implemented which involves testing by RT-PCR at the time of admission of all patients in the emergency room, their isolation respecting separate circuits until the result is obtained, simultaneously with the beginning of the appropriate treatment. If surgery is required immediately, it was performed by treating the patient as SARS-CoV-2 suspect, with all the precautions required by this: proper equipment of PPE in the operating room, avoidance as much as possible of aerosol-generating methods, including laparoscopic surgery, according to the recommendations of the national endoscopic surgery company ARCE in force during the analyzed period. When it was possible to delay the intervention for 24 hours until the result was obtained, in case of negative, the patient was operated laparoscopically, with standard PPE. If the test confirms the infection, the patient was transferred to one of the hospitals designated as a COVID-support hospital and further treated according to the guidelines in force.

Study group analysis

During April-June 2020, during the COVID-19 pandemic, the number of hospitalized cases for acute cholecystitis and other acute manifestations of GD was significantly lower than in the same period last year (21 vs 49 patients). Of the total presentations at the emergency room during the COVID-19 pandemic, only a percentage of 27.6.% agreed with the hospitalization (vs 48.5% in 2019), the rest expressing their request for conservative treatment.

The sex ratio was similar in the 2 groups (F: M = 2: 1), but the incidence of patients treated with rural origin was lower, this could be correlated with the travel difficulties imposed by the legislation during the state of expedite. The average age was higher in 2020, but statistically insignificant (64 vs 56 years).

Regarding the clinical forms, in both study groups the main form of presentation was acute catarrhal cholecystitis (52.4% vs 63.2%). We note, during the SARS-Cov-2 pandemic, the absence of mild forms of biliary colic, with increasing incidence of complicated forms, mainly hydrops (23.8% vs. 4.1%, $p < 0.05$) and angiocholitis (19% vs. 4.1%, $p < 0.05$).

From the analysis of associated comorbidities, we notice the increase of the share of cardiovascular diseases and diabetes in patients hospitalized during the pandemic, these diseases increasing the potential for aggravation of the general condition in patients with acute cholecystitis, making them unsuitable for conservative management.

Table 1: Comparative analysis of patients with acute manifestations of GD during the COVID-19 pandemic compared to the same period last year: demographic data, clinical forms at hospitalization, comorbidities

	April-June 2020	**April-June 2019**
Number	21	49
Male	33.3%	36.7%
Female	66.7%	63.3%
Urban/Rural	6:1	4:1
Age	64+/-3.2 years	56+/-2.7 years
Clinical form		
Biliary colic	0	8 (16.3%)
Acute cholecystitis		
- Cataral	11 (52.4%)	31 (63.2%)
- Phlegmonous	1 (4.7%)	2 (4.1%)
- Gangrenous	0	1 (2%)
Hydrops	5 (23.8%)	2 (4.1%)
Pio-cholecystitis	0	1 (2%)
Cholecistopancreatitis	1 (4.7%)	2 (4.1%)
Angiocholitis	4 (19%)	2 (4.1%)
Associated pathology:		
Obesity	6 (28.5%)	10 (20.4%)
Adherential Syndrome	5 (23.8%)	16 (32.6%)
Cardiac pathology	6 (28.5%)	6 (12.2%)
High Blood pressure	6 (28.5%)	16 (32.6%)
Diabetes	5 (23.8%)	3 (6.1%)
Gastritis/ Dyspeptic syndrome/Ulcer	3 (14.3%)	5 (10.2%)
Bronchopulmonary chronic obstructive disease	2 (9.5%)	0
Recent cerebrovascular accident	1 (4.7%)	0
Hepato-splenomegaly. Port vein thrombosis	1 (4.7%)	0
Hiatal hernia	0	1 (2%)
Neuropsychiatric disorders (epilepsy, drug addiction)	0	2 (4%)

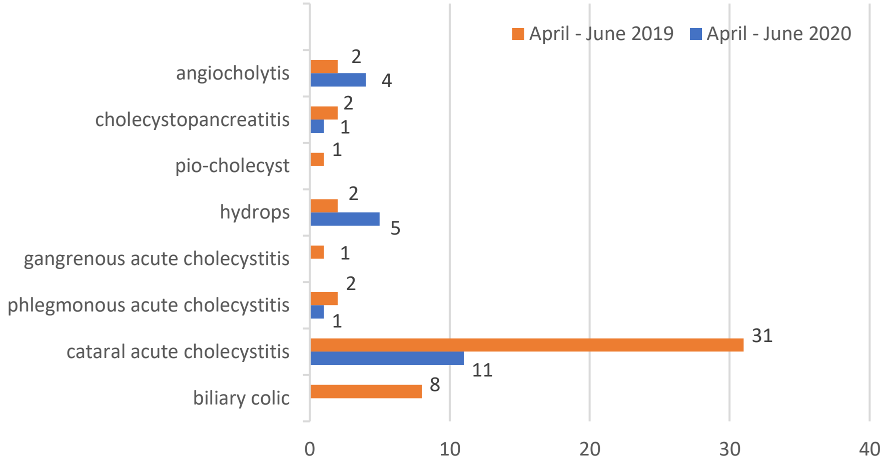

Figure 1: Comparative data for clinical forms during Covid-19 pandemic vs non-COVID period

After admission, all patients in the pandemic group were tested for Sars-CoV-2 infection and were hospitalized in a COVID-19 suspect area, with separate circuits from the rest of the department. Medical therapy was initiated, depending on the clinical form, with spasmolytics, analgesics, antibiotics and hydro-electrolytic rebalancing. In 20 of 21 cases, surgery could be delayed for up to 24 hours until the absence of COVID infection was documented. In one case, a piocholecyst with imminent of perforation was operated on in an immediate emergency, by open approach, and a cholecystectomy and subhepatic drainage were performed, with a slowly favorable evolution. In a case diagnosed with angiocholitis, SARS-CoV-2 positive, the patient was transferred for ERCP to a surgery department at a COVID-19 support hospital, evolving favorably under minimally invasive treatment.

Table 2: Therapeutic management and postoperative outcome in the COVID-19 pandemic group vs control group.

	April-June 2020	April-June 2019
% surgery	11 cases (52%)	35 cases (71%)
Type of surgery:		
LC	18 (85.7%)	30 (85.7%)
Conversion	0	2 (5.7%)
OC	1 (4.7%)	0
ERCP	1 (4.7%)	3 (8.6%)
ERCP+LC	1 (4.7%)	0
Hospital days	6.62	5.6
Postoperative complications:		
Deaths	2 (comorbidities)	0
Bleeding	1 (conservatory)	1
Infection of the wound	0	0

LC: laparoscopic cholecystectomy; OC: open cholecystectomy; ERCP: Endoscopic retrograde cholangiopancreatography

Regarding therapeutic management, there is an increase in cases that benefited from conservative treatment during the pandemic (48% vs. 29%). For operated patients, laparoscopic cholecystectomy was the main option, performed in 85.7% in both groups, except that during the pandemic, the intervention was delayed 24-48 hours to obtain confirmation of the absence of SARS-CoV-2 infection. There were no conversions for the pandemic group, a possible explanation being the better documentation of cases and the favorable effect of early medical therapy in cases with an increased risk of conversion due to local inflammatory anatomical changes.

The average hospital stay was slightly increased, but statistically insignificant, a possible explanation being the timing related to RT-PCR, but also the higher incidence of comorbidities and more severe forms of treated patients. The latter aspect also explains the higher rate of postoperative deaths (9.5% vs 0%), being related to cardiovascular and metabolic decompensation through the associated countries, in elderly patients.

DISCUSSION

The COVID-19 pandemic had a major impact on the management of acute gallstones. During this period, the proportion of cases treated conservatively increased, either outpatient, in the case of patients who refused hospitalization, or in hospitalized patients. This is communicated by similar studies conducted in Spain. Italy, UK or USA, also countries with a significant number of SARS-CoV-2 infections nationwide [1, 14-19].

One of the causes is the reluctance of patients to go to the emergency room or to consent to hospitalization for fear of infection. Harnett et al. estimates in this regard a decrease of up to 50% in the presentation of patients in the emergency room in the US during the pandemic [20]. On the other hand, given the increased pressure on health systems, but also of studies that show a bad outcome in surgeries performed on COVID + patients during the incubation period, international practice guidelines recommend conservative management and avoidance of surgery, if safe for the patient [6, 7, 12, 22-25].

Another important aspect is the reluctance to laparoscopic surgery, due to the possibility of aerosolization of surgical plume and CO2 at pneumoperitoneum desufflation [4]. Preoperative testing of patients is encouraged, as far as resources allow, however studies show a 30% chance of false-negative results, which can have unfavorable consequences for both the patient and the medical staff [26]. Considering possible presence of the infectious agent in blood, feces and intestinal wall and to avoid leakage near the trocar orifices, the use of low pneumoperitoneum pressure and low energy levels during electrocautery.

Regarding gallstone disease, laparoscopic cholecystectomy has established itself worldwide as a gold-standard, due to its indisputable advantages related to the reduction of operative complications, early recovery and reduced hospitalization time. Even during the COVID-19 pandemic, when the open approach was encouraged due to avoiding aerosolization, laparoscopic cholecystectomy remained the preferred technique in surgical practice in our department, being practiced in 87.5% of cases. Similar results are reported by Manzia, Narvaez and Kabir [1, 17, 27]. Moreover, Flemming and Kabir show that SARS-CoV-2 is not present in bile, gallbladder samples and peritoneal fluid [27, 28]. These preliminary findings suggest that the potential infectious risk for operating theater staff and surgeons during open and laparoscopic operations in SARS-CoV -2 patients is lower than initially expected.

Another observation found in the present study is the increase in the severity of cases hospitalized and operated during the SARS-Cov-2 pandemic compared to the same period last year. Gallstones disease, even if not an emergency, should receive surgical treatment when symptomatic. Neglecting this extremely common pathology can increase the incidence of severe, life-threatening complications such as cholangiopancreatitis or angiocolitis [28-33].

Additionally, a more advanced disease at the time of surgery may result in increasingly morbid operations, which are associated with prolonged hospital stay and higher costs. Since the global healthcare community has never faced a dramatic scenario such as the COVID-19 pandemic, it is difficult to forecast the effects of untreated GD and the development of its related complications during and after COVID-19 [1].

CONCLUSIONS

In light of recent findings, but changes to the surgical protocol are required to increased safety for medical personnel.

We maintain that laparoscopic cholecystectomy remains the gold standard for acute cholecystitis, even in the COVID-19 pandemic, as it guarantees the best outcomes for the patients.

Conservative management may be an option for mild cases, but it carries the risk of recurrence of symptoms and an increased incidence of severe complications.

Clinical aspects in implant fixed prosthodontics oral rehabilitation. Case report

A.M.C. Țâncu[1], E. Preoteasa[1], C. Preoteasa[1], M. Pantea[1], M. Meleșcanu Imre[1]

Abstract*:* *Benzodiazepine overdose has various clinical manifestation, mainly regarding the central nervous system (CNS), cardiac and respiratory side effects, but rarely results in significant morbidity and mortality. Acute benzodiazepine poisoning results in dizziness, ataxia, nystagmus, dysarthria, hypoxia, hypothermia, bradycardia, hypotension, apnea, pulmonary aspiration, respiratory depression, coma, cardiopulmonary arrest and death. Anyway, deep nonresponsive coma should be investigated for additional etiologies. On the other hand, human transmissible prion disease has a fatal outcome with no specific treatment.*

Keywords: *implants, osseous integration, staging, fixed prosthesis*

INTRODUCTION

Each year endoosseous dental implants gain greater acceptance among clinicians and patients. This has come about for several reasons, including excellent success rates published in long-term studies, improvements in fixture and abutment designs, more predictable surgical placement techniques, and increased consumer desire to have tooth replacement. Regardless of the implant system, the placement and functional success of endo osseous implants is greater than 90%) [1]. Fixed prosthodontic on implants is the most desirable treatment for the patients among the treatments on implants. When transforming a partially edentulous patient in a complete edentulous one, the transition difficult period can be avoided by keeping some teeth for fixed provisional, until the osseous integration of the implants is accomplished and the final prosthetic can be done [3]. In this regard, the importance of restoring patients with functionality during the implant healing period has grown in recent decades [7].

This paper presents a staged protocol of the patient's treatment that made the case easier to manage and offered a better comfort in the transition period.

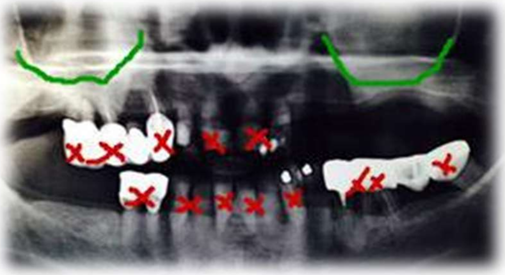
CASE REPORT

Material and method

T.S., a 66 years old female patient, with a general medical history of chronical C hepatitis, presented with a mucocell in the sinus cavity and a T,L-T maxillary edentation and L-T mandibular edentation, with inadequate fixed restorations, both in upper and lower jaw. An accurate and complex clinical examinations wad performed, including the prosthodontic, implant – surgical assessment, panoramic radiograph and computed tomograms for both jaws. The intermaxillary relationships were carefully examined and the OVD was recorded (5.7 cm).

A comprehensive treatment plan was proposed and decided, following the conclusions from the diagnosis findings. Thus, all the remaining teeth were in a poor dental status and needed to be extract, but in a staged approach, as in figure 1.

Figure 1: Initial dental status

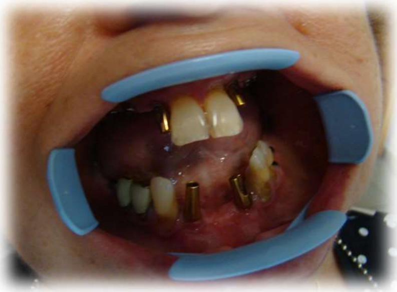


The 1st step was the surgical one on the maxillary arch. So, after CT, Rx measurements and evaluation of bone volume and density related to prosthetic planning dental implants position was decided the placement of 3 implants (Superline, Dentium) (2.2/2.4/2.6). Prior to this was performed the left sinus mucocel evacuation. Meantime was performed also the internal sinus lifting with mineral bone grafting (Osteon, Dentium).

The 2nd surgical step. After the healing period (2 months), right sinus lifting was performed with same materials and were placed 3 implants (1.4/1.5/1.6).

By the time of implants osseous integration, the 11 and 21 were kept in order to provide patient's minimal aesthetic and functional comfort. Provisionals, immediate loading – nor fixed or removable couldn't be used due to bilaterally sinus lifting with bone grafting materials and the bone density. (Figure 2)

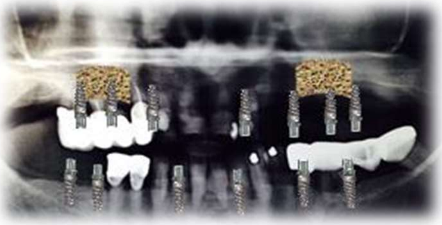
Figure 2: The clinical situation before the 3rd step



Meanwhile the 6 upper jaw implants osseous integration, the 3rd surgical step, consisted in the placement, on the lower jaw, of 2 implants (4.6/4.7) and 1 implant in the upper jaw (1.2), all of them prosthetic driven. After the evaluation of the occlusal vertical dimension (OVD) that we recorded and preserved, the vertical space was assessed as well as mandibular implants positioning in order to obtain correct occlusal relationships.

In the 4th surgical step the insertion of 2 frontal mandibular implants (3.2/4.2) and 2 left lateral mandibular implants (3.4/3.6) was performed. 3.3/ 3.4/4.3/4.4/4.5 for fixed provisional. The extracted teeth were: 1.2/1.3/1.5/1.6/2.2 initially and just before the implants uncovering, 1.1 and 2.1, in the upper jaw and 3.1/3.2/3.5/4.1/4.2/4.6/4.8 in the lower jaw and 3.3/3.4/4.3/4.4/4.5 were used for provisionals. (Figure 3)

Figure 3: Panoramic radiograph after the implant's placement



RESULTS AND DISCUSSIONS

Due to the case complexity, because of the surgical aspects (13 implants insertion), bilaterally internal sinus lifting with bone grafting and the evacuation of a mucocell, related to the prosthodontic ones, meaning the complete fixed bimaxillary rehabilitation, have made the treatment to last 1,5 years until the final prosthetic rehabilitation that we will describe next.

Due to the staged surgical approach, there was no possibility to split the final prosthetic work in more segments, nor in maxilla or mandible, so we produced 2 full – arch restorations on implants.

The idea of the final prosthetic treatment was to rehabilitate simultaneously the 2 jaws in order to split optimally the vertical prosthetic space. So, after all implant's uncovering and the last teeth extraction the healing abutments were applied and after 10 days the impression was taken. Monopren transfer (Kettehbach) was used as impression material, in an open individual tray technique, using transfer abutments.

The work casts were obtained with the analogue implants in their position. On this casts, occlusion rims were made for the intermaxillary relationship registration. All the steps were performed in order to establish accurately the occlusal and intermaxillary relationships: the vestibular curve of the upper occlusion rim was esthetical and phonetic established.The occlusal plane's level and direction were established using the usual methods and also the patient s youth photo, that provided a lot of useful information, such as the visibility of the 6 frontals. The initial correct OVD was kept and the 2 rims were fixed in the correct CR position. The information about the facial midline, the smile line and canine lines, together with other information regarding the teeth colour, size, form, arrangement and positioning were transmitted to the laboratory.

After the intermaxillary relationship registration, the dental lab produced the metal frame of the prosthetic work. The trial of the metallic part was done related to the axial and cervical marginal fit. With the patient s agreement, the last esthetical decision were taken, regarding the colour and form of the artificial teeth, to provide the dental lab all the information for the ceramic application. In the dental lab Vita ceramic layers were applied.

The try-in of the prosthetic work was done, aesthetic, phonetic and occlusal relationships and intermaxillary, horizontally and vertical. Also, occlusal adjustments were performed. Then the 2 fixed prostheses were glazed and polished.

The final work was provisional cemented and then definitively (Figure 4).

Figure 4: Final result

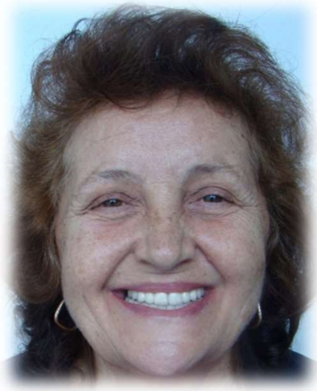


Figure 5: A 3 year follow up

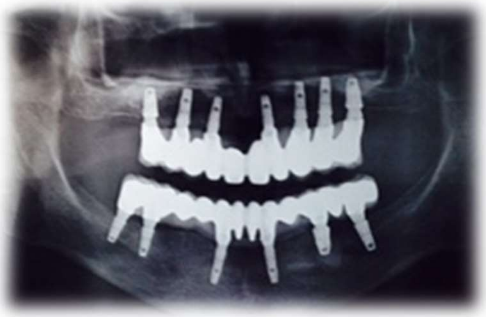

Figure 6: Final occlusal relationship

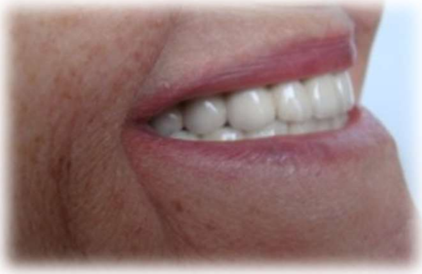

The follow-up was done, after 6 months and then after 3 years, and the results can be observed on the panoramic radiograph and indicates a very good situation.

CONCLUSIONS AND CLINICAL IMPLICATIONS

For many patients, as for the patient s case that we described previously, the transition between the dentate state and the completely edentulous state, with removable provisional is difficult to accept. That ⍰s why we choose a staged approach for our case, with strategic extractions and implants applied in 4 surgical different phases. The provision prosthetic was a fixed one, the major advantage of this treatment protocol. The treatment planning in such complex cases represents a challenge for the implantologist and prosthodontist and for the patient and our presented protocol facilitates the transition from a destroyed dentition to a full-arch reconstruction.

VARIA

Clinical characteristics and management evolution of cholelithiasis in a pediatric population: 123 cases experience

Gabriel Stanciu[1], Ancuta Cardoneanu[1], Sorin Nedelea[2]

Abstract: *Introduction: The incidence of cholelithiasis has recently increased in the pediatric population, although it remains a rare disease among children. The purpose of this study is to highlight the management and the appropriate time to perform surgery.*

Materials and Methods: We performed a retrospective study over 10 years (2010-2010) and we found 123 patients who presented with biliary lithiasis and who underwent surgery in our department. We divided the study population into two groups depending on the time of admission and we found that in the 2010-2015 period we had a number of 33 patients, while in the last 5 years we admitted 90 patients with this diagnosis. Patients with other conditions such as bile duct atresia, choledochal cyst, hepatoblastoma that required a cholecystectomy were excluded from our study.

Results: After analyzing the two groups we concluded that the number of surgical procedures increased from 33 to 90, which represents a 2.6 times increase. There was no significant difference between the two groups regarding the average age on admission (12.6 +/- 3.37 in the first group vs. 13.91 +/-3.34 in the second group). Surgical management of lithiasis cholecystitis registered an important difference in the two groups. In the first group, 9 patients (27.3%) underwent classic cholecystectomy while 24 (72.7%) – patients benefited from the laparoscopic approach, while in the second group just one patient underwent open surgery with 89 (98.9%) patients undergoing laparoscopic surgery. The percentage of patients who benefited from surgery in the same hospitalization remained high in both groups studied with a statistically significant p-value (p = 0.0417).

Conclusion: The number of cases with cholecystitis and lithiasis is increasing in the pediatric population. Surgical management for these patients has become similar to that of adult patients, with minimally invasive surgery becoming the gold standard approach.

INTRODUCTION

Gallbladder disease is one of the most common and costly digestive diseases that require hospitalization. Gallstones are more common in the adult population and remain relatively uncommon in children. However, the incidence of gallbladder disease in children has markedly increased over the last several decades. Although uncommon during the first years of life, it is being diagnosed with increasing frequency in neonates and infants, probably because of the widespread use of ultrasonography [1, 2].

There are a few well-known risk factors for pediatric cholelithiasis such as hemolytic conditions, prematurity,

prolonged parenteral nutrition, obesity, and puberty (for girls) [1]. Although in the past, biliary lithiasis was most often associated with benign hematological disease, nowadays the prevalence of non-hemolytic gallstone disease has been shown to increase as the prevalence of obesity also increases [3].

Even if for adults cholecystectomy is a routine procedure, the same cannot be stated for pediatric patients. According to early reports over recent years, there has been a significant increase in pediatric cholecystectomies due to the rising incidence of lithiasis cholecystitis [4].

The primary pediatric indication for cholecystectomy is biliary dyskinesia or symptomatic cholelithiasis. One reason for the increase in the frequency of pediatric cholecystectomy may be that laparoscopic cholecystectomy is commonly accessible. Laparoscopic cholecystectomy has become the gold standard in the treatment of symptomatic gallstones. The major advantages of laparoscopic cholecystectomy include less postoperative pain, less time required for hospitalization and recovery, and better cosmetic results [5].

This study is a retrospective analysis of patients under 18 years old, following the characteristics, evolution, and surgical management of the patients diagnosed with lithiasis cholecystitis who underwent cholecystectomy at Grigore Alexandrescu Emergency Pediatric Hospital of Bucharest in the pediatric surgery department.

MATERIALS AND METHODS

Patients who were admitted to our department for cholecystectomy between January 2010 and December 2020 were taken into consideration and included in this retrospective study. We took into account patients who presented in our service either through the emergency room, as acute cholecystitis, or in a scheduled manner.

The main inclusion criteria for patient selection from our database were patients under 18 years old, who underwent cholecystectomy for lithiasis cholecystitis. Patients with hepatoblastoma, choledochal cyst, congenital biliary atresia, and other conditions that required cholecystectomies but the cause was not lithiasis were excluded.

Data for this review was obtained from the Pediatric Surgery Department's database. One hundred and forty-one cholecystectomies were performed during this period but after we applied the exclusion criteria the total amount of cases remained 123.

After we have considered the variables for all the patients, we divided them into 2 groups of interest depending on the period in which they presented in our department (group 1: 2010-2015 and group 2: 2016-2020) to investigate the trend over time.

Afterward, patients were divided according to their diagnosis into symptomatic and asymptomatic. Those symptomatic were further divided into uncomplicated (diffuse abdominal pain, biliary colic, nausea, and vomiting, without any inflammatory signs) and complicated (which associated choledocholithiasis, biliary pancreatitis, or acute abdominal pain in the upper quadrant in association with inflammatory signs like fever, leukocytosis, and high CRP). Patients who were referred to the emergency department with acute cholecystitis due to lithiasis have benefited from surgical treatment either during the same hospital stay (if the liver enzymes and amylase decreased) or less than a month after the acute event in most cases. For those who were diagnosed with gallstones accidentally by ultrasonography, the conservative treatment (ursodeoxycholic acid-dose 10 mg/kg/day) was the first choice and if during subsequent evaluation still presented lithiasis, cholecystectomy was taken into consideration.

Abdominal ultrasound was performed for all patients. If an impacted calculus in the common bile duct was found during an ultrasound, magnetic resonance cholangiography (MRCP) or endoscopic retrograde cholangiopancreatography (ERCP) were then performed.

We also took into consideration anatomical abnormalities as a risk factor for lithiasis and found 3 cases with abnormal anatomy of the gallbladder. Criteria like surgical approach, intraoperative cholangiography, postoperative complication, and days of hospitalization and rehospitalization were also taken into account. Postoperative follow-up ranged from 6 months to 2 years.

For data collection, analysis, processing, and filtering we used Microsoft Excel. Comparisons between both 1st and 2nd periods were made using a two-tailed Student t-test for continuous variables and a one-sample t-test for categorical variables with a p-value ≤ 0.05 defined as significant.

RESULTS

This study was conducted on 123 patients with lithiasis cholecystitis who underwent either open or laparoscopic cholecystectomy. Before dividing the cohort into two main groups, we can easily observe the ascending trend of lithiasis cholecystitis cases with cholecystectomy over the 10 years (Figure 1).

Figure 1: Number of lithiasis cholecystectomies

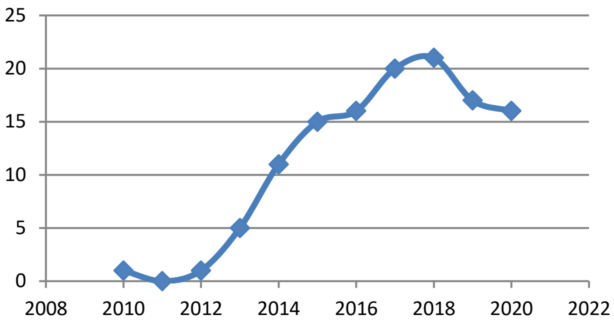

Figure 2: Mean age at the time of diagnosis in both groups

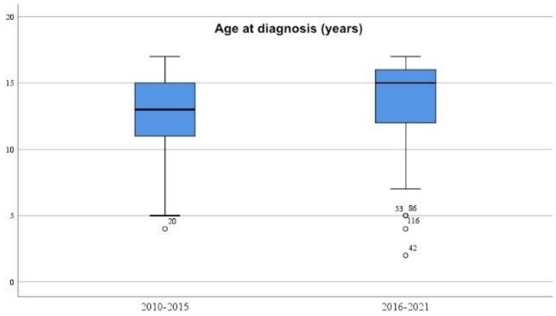


After the cohort was divided into two main groups according to the period, the median age registered a 2-year increase in the average age in group 2 compared to group 1 (p=0.2029) (range, 1 year to 17 years and 11 months) (Figure 2).

The vast majority of children were females in both groups (group 1 – 63.63%; group 2 – 66.66%). Taking into account the background, there is a slight increase in rural patients in group 2, but patients from the urban background are still the majority.

Table 1: Preoperative variables

Variable	**Category**	**Group 1 (G1) n=33 (100%)**	**Group 2 (G2) n=90 (100%)**	**P value <0.05** (One sample t-Test)	**P value <0.05** (Tow sample paired t-Test)
Gender	Male	12 (36.36%)	30 (33.33%)	0.0393	0.1266
	Female	21 (63.63%)	60 (66.66%)	0.0756	
Age (years)	Mean age (SD; Median)	12.6 (3.37; 13)	13.91 (3.34; 15)	-	0.2029
Background	Urban	20 (60.6%)	47 (52.22%)	0.0262	0.0005
	Rural	13 (39.4%)	43 (47.77%)	0.1239	
Comorbidities	Obesity	13 (39.4%)	37 (41.11%)	0.0744	0.002
	Hematologic diseases	1 (3%)	9 (10%)	0.4226	
	Neurologic diseases	0 (0%)	6 (6.66%)	0.6346	
	None	19 (57.6%)	38 (42.22%)	0.0054	
Clinical presentation	Simptomatic	23 (69.7%)	46 (51.11%)	0.0054	0.3454
	Asimptomatic	10 (30.3%)	44 (48.88%)	0.2245	
Simptomatic	Complicated	2 (8.7%)	10 (21.73%)	0.2672	0
	Uncomplicated	21 (91.3%)	36 (78.26%)	0.0003	
Pre- or intraoperative investigation	Ultrasonography	33 (100 %)	90 (100)	0.0619	-
	MRCP	1 (3%)	5 (5.55%)	0.2672	
	ERCP	0 (0%)	6 (6.66%)	0.6346	
	Colangiography	2 (6 %)	1 (1.11%)	0.0054	

Obesity is the most common comorbidity in both groups (p=0.0744), also the number of patients presenting with cholelithiasis associating comorbidities is higher, this being statistically significant (p=0.0054). In our study group, we took into consideration comorbidities like obesity (51), hematological (10), and neurological diseases (6). The main hematological disease was hereditary spherocytosis (10) and in the case of neurologic diseases were epilepsy (3) and spastic tetraparesis (3). One patient presented both epilepsy and spastic tetraparesis. A 20% increase in the number of patients diagnosed during a routine ultrasound examination can be observed, but the number of symptomatic patients is still high (group 2 - 51.11%; p = 0.0054). Even though the ultrasonographic examination is widely performed and asymptomatic patients are diagnosed early, the percentage of patients with complicated cholelithiasis has doubled (group 1 – 8.7% vs group 2 – 21.7%).

Ultrasonography is the main method of diagnosis of this pathology. However, there is a doubling of the percentage of patients who received MRCP (group 1 - 3% vs group 2 - 5.55%) and an increase in the percentage for ERCP (group 1 - 0% vs group 2 – 6.66%) in detriment of cholangiography which was preferred in the first period of our study (group 1 - 6% vs group 2 – 1.1%). Just the patients who associated choledocholithiasis symptomatology required the magnetic resonance cholangiopancreatography exam. Three patients with choledocholithiasis underwent ERCP before cholecystectomy and the other 3 has a cholangiography performed during cholecystectomy surgery.

Regarding the moment of surgery, the results are almost similar in both groups as can be seen in Table 2. There is an increase in the number of cholecystectomies (the difference between those two groups is about 2.6) taking into consideration the availability of radiological examination, especially ultrasonography and laparoscopic approach accessibility. Laparoscopic surgery was performed in 98.8% of patients in group 2 and 72.7% of patients in group 1 (Table 2).

Table 2: Surgical management

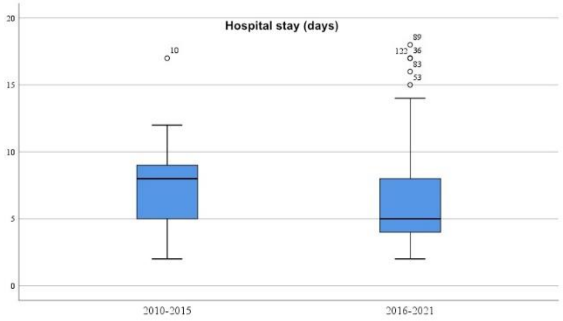
Variable	Category	Group 1 (G1) n=33 (100%)	Group 2 (G2) n=90 (100%)	P value <0.05 (One sample t-Test)	P value <0.05 (Tow sample paired t-Test)
Moment of surgery	Same hospitalization	19 (57.5)	48 (53.3)	0.0417	0.0004
	Less than a month	7 (21.2)	23 (25.5)	0.1216	
	More than a month	7 (21.2)	19 (21.1)	0.0605	
Surgical approach	Laparoscopy	24 (72.7)	89 (98.8)	0.1643	0.8698
	Clasic	9 (27.7)	1 (1.11)	0.4226	
	Converted laparoscopy	0 (0)	0 (0)	-	-
Priority	Urgent	19 (57.5)	48 (53.3)	0.0417	0
	Elective	14 (42.4)	42 (46.6)	0.091	
Postoperative complications	Bleeding or Local hematoma	1 (3.03)	4 (4.4)	0.1912	0.5294
	None	32 (96.9)	87 (96.6)	0.061	
Reintervention		1	2	0.0054	
Hospital stay (days)	Mean/Median	8.21/8	7.04/5		
Readmission	Yes	1 (3.03)	5 (5.5)	0.2672	0.4894
	No	32 (96.9)	85 (94.4)	0.0546	

The conversion was not considered in any patients. One patient underwent laparoscopic emergency surgery and a subtotal-cholecystectomy was performed due to the inflammatory process which did not allow safe dissection of the elements of the hilum. This patient underwent a second open surgery after 5 months during which the remaining gallbladder was removed.

In both groups, the number of emergency surgeries remains higher than the number of electively operated patients (Table 2). Postoperative complications were recorded in almost 7% of cases and they were only hemorrhagic complications. Three patients required a second surgery and in two cases the source of the active hemorrhage was the gallbladder bed, while in the third case a large hematoma was found without signs of active bleeding. Ultrasonography revealed hematoma in the gallbladder bed in 2 other patients, but they were treated conservatively. No complications such as bile leakage or bile duct injury, infection, or postoperative wound dehiscence were highlighted. No deaths were recorded in our study.

The median of hospitalization days in group 1 was 8 days, significantly higher when compared to group 2 where the median was 5 days (Table 2, Figure 3).

Figure 3: Mean hospital stay in both groups



There is a slight increase in the percentage of patients readmitted in group 2 compared to group 1 (group 2-5.5%; group 1-3.03%), with the mention that from the patients readmitted in group 2 one needed surgical reintervention while the rest received symptomatic treatment. An overview of the time of intervention, depending on the patient's condition at presentation (acute or chronic), shows that most acute patients required surgery during the first presentation, compared to chronic patients who initially benefited from conservative treatment (Table 3).

Table 3: Moment of intervention depending on the general condition of the patient

	Same hospitalization	Less than a month	More than a month
Acute	39	10	4
Chronic	-	20	23

**27 of the chronic patients were previously diagnosed in other medical centers without being able to specify exactly the time of diagnosis, for this reason, they were excluded from this analysis.*

Considering the number of hospitalization days, we divided the patients into 2 groups, acute and chronic, and the results showed an average of 8.86 days for acute patients, compared to 5.58 days for chronic ones (Table 4).

Table 4: Mean of the days of hospitalization depending on the general condition of the patient

	Acute	Chronic
Days of hospitalization (mean)	8.86	5.58

Also, depending on the number of days of hospitalization, patients were divided into two groups regarding the surgical approach (classic and laparoscopic) resulting in a decrease of 2.55 of the average number of days of hospitalization for those operated laparoscopically (Table 5).

Table 5: Mean of the days of hospitalization depending on the surgery approach

	Classic	Laparoscopic
Days of hospitalization (mean)	9.7	7.15

DISCUSSION

Compared to adults, the prevalence of lithiasis cholecystitis is lower in children, so cholecystectomy is less common in this age group. Recently, several studies reported that cholecystitis and cholelithiasis are being diagnosed with increasing frequency in infancy, childhood, and adolescence and the incidence is reported to be between 0.15 & 0.22% [1]. As most cases of cholelithiasis are asymptomatic, the prevalence of this pathology cannot be correctly assessed. However, the symptoms that may occur are diffuse abdominal pain, biliary colic, nausea, and vomiting, without any inflammatory signs or by complications like choledocholithiasis, biliary pancreatitis, or acute abdominal pain in the upper quadrant in association with inflammatory signs like fever, leukocytosis, and high CRP. Comparing the two groups from our study, the number of cholecystectomies increased from 33 to 90, which represents an increase of 2.6 times higher in group 2, a result that is comparable to other studies [3]. This may be due to the frequent use of abdominal ultrasound in children with abdominal disorders which recently has resulted in the diagnosis of gallstones in a large number of asymptomatic children [1]. Also, the high number of cholecystectomies can be the result of the widespread use of laparoscopy.

As in the literature, there was a higher incidence of cholelithiasis in females (group 1 – 63.63%; group 2 – 66.66%). This can be explained by the hormonal changes that occur during puberty, with an increase in the saturation of cholesterol in bile [6, 7]. What strengthens our assumption is that the average age of cholelithiasis in both groups is around puberty (group 1 – 12.6 - group 2 – 13.9).

In contrast to other studies in which the incidence of cases of cholecystitis in patients with hematological diseases seems to decrease over time, in our study, there is a 7% increase in group 2 compared to group 1. However, the percentage of patients who have a hematological disease as a risk factor remains low compared to those presenting with obesity. Similar to other series, most of our patients were obese (group 1 – 39.4%, group 2 – 41.1%).

In general, the percentage of pediatric patients with symptomatic cholelithiasis is around 60% [2], similar to our data. However, even though the number of symptomatic patients is higher, our data showed a decrease of approximately 18% of symptomatic patients in group 2 compared to group 1, and an increase of 18% in asymptomatic patients. This is probably also the result of the widespread use of ultrasonography so that many patients with gallstones end up being diagnosed before the onset of symptoms.

The percentage of complicated cases was almost 3 times higher in the second group of our study, while the percentage of uncomplicated cases decreased. One theory that would explain this trend is that the diagnosis is established mainly in the asymptomatic phases of the disease, and in an attempt to treat them conservatively with ursodeoxycholic acid, the stones reach a diameter that allows them to migrate along the bile ducts and obstruct them.

In the adult population, ERCP has gained ground versus open exploration of the common bile duct, thus leading to a decrease in their risk of injury [8] and the same can be seen in our cohort, where in the last 5 years the number of pediatric patients undergoing ERCP has also increased. Gee et al. propose performing cholecystectomy and ERCP at the same time, arguing that this method is a safe way to treat choledocholithiasis, without increasing the rate of postoperative complications, and additionally it is a cost-effective method [9].

Acute cholecystitis due to lithiasis was considered a relative contraindication to laparoscopic cholecystectomy in the early years of the development of this technique but was later shown to be safe in the treatment of acute cholecystitis [10, 11]. Nowadays, the management of lithiasis cholecystitis in the pediatric population, as in the case of adults, consists in using laparoscopy as the main method of surgical treatment. This method is preferred to open cholecystectomy because it has many benefits such as reduced costs by reducing hospitalization days and the use of painkillers, as has been shown in other studies [12, 13, 14]. The fact that in the last decade laparoscopic treatment is used as the main approach in the case of cholelithiasis is also shown in our study.

The right time to perform the surgery in the case of patients presenting to the emergency room remains to be debated. While some studies suggest performing surgery after 6-9 weeks of conservative treatment in acute patients to reduce the acute inflammatory process, Lo et al. and Casillas et al. observed that conservative treatment of lithic cholecystitis for a long period leads to the formation of fibrotic tissue adhesions between the gallbladder and the surrounding structures due to inflammation and edema, which makes dissection difficult. They advocate that early laparoscopic cholecystectomy performed with appropriate timing will facilitate the dissection and reduce the possibility of late complications [10, 15, 16]. The indication for early cholecystectomy is supported by various publications, which report a 5% increase in complication risk for every 10 days surgical treatment is postponed [17-21]. Regarding postoperative complications in our cohort, no complications other than hemorrhagic ones were identified and even these were present in a small number of patients. Postoperative hospital stay was long (mean 8.21 days in group 1 and 7.04 days in group 2), although no major complications were noted.

CONCLUSION

The number of cases with cholecystitis and lithiasis is increasing in the pediatric population. Surgical management for these patients has become similar to that of adult patients, with minimally invasive surgery becoming the gold standard approach.

Clinical profile of Mediterranean fever – Study from an Indian tertiary care center

Varsha Somakumar[1], V.S. Srikanth[2], Cibi Manoharan[1], Vishal Marwaha[1], V.R. Mujeeb[2], M.G.K. Pillai[1], Anna M. Bastine[1], Mehana Ashraf[1]

Abstract: *Introduction: Brucellosis is a zoonotic disease which is also known as Mediterranean fever. It is acquired from the handling of infected animals or consuming contaminated milk or milk products. The incubation period varies from 1-3 weeks to several months before clinical disease appearance and it shows multiorgan involvement. This study focuses on the varied presentation of this disease and laboratory findings. Materials and Methods: This is a retrospective study, where the past 15 years data of cases diagnosed with brucellosis was studied in a tertiary care center in South India. Patient demographics, clinical presentation, duration of stay in the hospital, hematological and biochemistry profiles were collected and analyzed in SPSS. Results: More number cases were found among the male gender (70%), mostly in the 20-40 years age group (40%). 95% of cases reported fever, 40% with arthralgia (29% generalized in nature), and 32% with a headache. A Positive Pearson correlation between CRP and NLR, and CRP and PLR were found, which was statistically significant. Mean laboratory values were documented. 37% of patients were found to have hepatosplenomegaly on ultrasound Conclusion: Most of the patients were admitted as cases with pyrexia of unknown origin. Our study focused on the different clinical presentations and laboratory findings of brucellosis and will help give a better understanding and outline during brucellosis case diagnosis and management in a cost-efficient manner.*

Keywords: *brucellosis, undulant fever, Mediterranean fever*

INTRODUCTION

Brucellosis is a zoonotic disease caused by bacteria of the genus Brucella. It is also known as undulant fever or Mediterranean fever [1]. Caused by Gram-negative coccobacilli, non-spore-forming and non-motile and aerobic; B. melitensis, B. abortus, B. suisare the important human pathogens. It is acquired from the handling of infected animals or consuming contaminated milk or milk products. Exposure is frequently occupational. Human brucellosis is either an acute febrile disease or a persistent disease with a wide variety of symptoms like night sweats, asthenia, insomnia, anorexia, and headache.

The disease is controlled by the routine practice of pasteurizing milk and milk products, as well as by comprehensive campaigns to eradicate the disease by destroying domestic animals which exhibit positive serologic reactions to brucellae. Vaccines providing some protection to cattle, sheep, and goats are available [2]. The incubation period of this infection is between 1-3 weeks but can take several months before clinical disease appearance [1]. The disease shows multiorgan involvement including musculoskeletal, digestive, urogenital, hematological, cardiovascular, respiratory, and central nervous systems [3]. According to the duration of symptoms, it can be classified

as acute (<8 weeks), sub-acute (8 to 52 weeks), and chronic (> 52 weeks).

Subacute brucellosis, typically presenting with undulant fever, described in endemic areas with localized infections such as epididymitis, orchitis, and osteoarticular complications, is most commonly seen. Osteoarticular involvement is the most common focal complication of brucellosis (10-85%) [4]. Sacroiliac joints are the most common site involved in younger patients; spondylitis and peripheral arthritis usually occur in older patients. Cardiovascular complications of brucellosis (endocarditis, myocarditis, and pericarditis) are rare (1% of cases) [5].

In humans, the most common route of entry of Brucella bacteria is through the gastrointestinal tract and it then localizes in the reticuloendothelial system. Hepatic enlargement is the most frequent gastrointestinal manifestation of brucellosis (32-63% of cases) [6]. Neurobrucellosis is the most serious complication of brucellosis with neither a typical clinical manifestation nor a specific cerebrospinal fluid (CSF) picture and mimics other neurological disorders leading to diagnostic dilemmas. The prevalence of Neurobrucellosis ranges from 1.7 to 10% of brucellosis worldwide [7].

This study aims to record the clinical features and cut off of certain laboratory values of human brucellosis cases in South India, for prompt diagnosis of the same.

MATERIALS AND METHODS

This is a retrospective observational study, where 15 years of data of patients diagnosed with brucellosis is collected in a pre-designed format. Details including demographics, clinical presentation, hematological and biochemistry profiles are collected and analyzed in SPSS. Inclusion criteria are patients diagnosed with brucellosis in our hospital, with positive IgM ELISA. Exclusion criteria include cases previously diagnosed from an outside hospital, patients who had taken the alternative form of treatment, etc to avoid bias in lab reports. Study design, data collection, and write-up were done in Amrita Medical College. Study analysis and review were done by V.S. Srikanth, using SPSS, where Pearson correlation and values of central tendency of the findings were recorded.

Data collection, analysis, and article preparation are done in accordance and with the permission of Amrita Institute's ethics review committee.

RESULTS

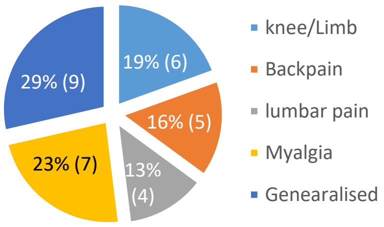
In our study, we found that 70% (54) were male and 30% (23) females, out of the total 77 cases. The age group of presentations were most in the 20-30 years group (22%); 30-40 years were 18% and remaining presentations were scattered across all other age groups (Table 1).

Table 1: Age distribution

Age	< 17 years	20-30 years	30-40 years	40-50 years	50-60 years	> 60 years
Number	13	17	14	10	11	12
% distribution	17%	22%	18%	13%	14%	16%

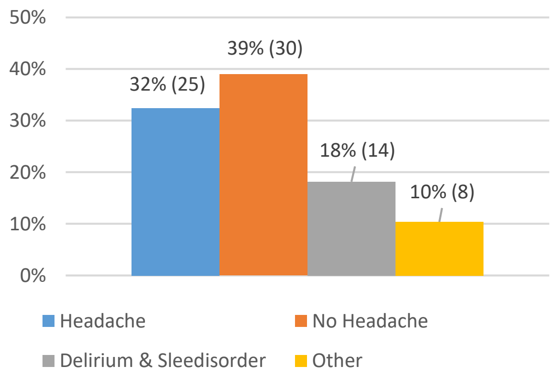
5 cases were reported outside Kerala. The hospital stay duration was a minimum of 3 days and a maximum of 30 days, with a mean duration of 10 days. Clinical presentation – Fever - 73 (95%) patients presented with fever, out of which 50 (68%) had a high-grade fever (102-104). The fever duration was a minimum of 5 days to a maximum of 120 days and a mean duration of 21 days. Arthralgia – 31 (40%) patients presented with severe arthralgia, rest had no features of arthralgia (Figure 1).

Figure 1: Arthralgia



The most common GIT presentation was Constipation and vague abdominal pain and headache were present in 32% (25) of patients (Figure 2).

Figure 2: CNS symptoms



Mean values of neutrophil, lymphocyte, platelet counts, red cell distribution width, mean platelet volume, C reactive protein (CRP), procalcitonin, hemoglobin, SGOT, SGPT, serum protein, albumin, sodium, potassium, creatinine, and IgM Elisa values were found (Tables 2 and 3).

DISCUSSION

A higher incidence of cases was seen among males in our study (54, 70.1%), comparable to similar studies [9, 10, 18].

The mean age of brucellosis patients in our study was 36.95+19.22 years, similar to the findings of Huseyin S et al. [19]. In another similar study done by Mahmood Nabavi et al. [7], the mean age was 39.59 ± 17.28 years, and the most prevalent age groups was 31–50 (42.1%), while in another study done by Akhvlediani T et al. [9], mean age was 39.9 (standard deviation = 15.1) years and 45% of participants were 21–40 years old, which is comparable to our result.

Common clinical presentations in our study were fever (73, 94.8%), arthralgia (31, 40.26%), and generalized pain and swelling with myalgia (33, 43%), consistent with other studies [18]. Abdominal pain, loss of appetite, loss of weight, vomiting, etc were seen in 34 (44.1%) cases, while other symptoms like headache, altered sensorium, and fatigue were seen in 28 (36.3%) cases. In a similar study done by Akhvlediani T et al. [9], the most frequent complaints were sweats (92%), joint pain (91%), aches (90%), malaise (90%), fatigue (87%), and rigors (86%), arthralgia (72%). Loss of appetite, weight loss, and arthritis was also observed in 46%, 44%, and 24% of participants, respectively. The most prevalent clinical manifestations of brucellosis were fever, anorexia, weight loss, low back, and muscle pains in the study by Mahmood Nabavi et al. [7] and another similar study done by Kazanasmaz H [11], arthralgia (45.8%), fever (≥38.5 C0) (28.6%), and malaise and fatigue (11.5%) were the most common complaints at the time of presentation to the hospital [4].

29% of the patients with arthralgia presented with back pain, consistent with the findings of the study by Tasova Y et al. [15] and Turan H [16].

Mean neutrophil, lymphocyte, NLR, platelets, PLR, RDW, MPV, and CRP was found to be 56.3, 31.8, 3.22, 303, 15.67, 14.95, 8.39, and 61.58 respectively in our study. In a similar study done by Aktar F et al. {12], Neu – 71, Lym – 16, Plt – 282, NLR – 4.1, PLR – 154, RDW – 16.2, MPV – 8.2, and CRP-28.1. NLR can be determined from routine blood differentials at no additional cost, it increases in inflammatory conditions and this increase is considered as an indicator of systemic inflammation [13]. Studies showed that platelets also play an active role in inflammation while having regulatory effects on the immune system [14].

A similar MPV of 8.6 and a mean platelet count of 246 were also seen in the study done by Okan DH et al. [14]. Thrombocytopenia and lower MPV values found in our study are consistent with findings of other similar studies [12, 14]. Considering the same, MPV values in combination with platelet counts might be useful in patients with brucellosis [14].

C-reactive protein assay is a helpful adjunct in the diagnosis of patients with brucellosis [17]. High levels of CRP (61.58), SGPT (93.3), SGOT (99.7) was seen in our study, similar to the high CRP (39%), high ALT (33%), and high AST (20%) found in the study done by Shi et al. [18]. A positive correlation between standard agglutination titer and SGOT and SGPT was found by Huseyin S et al. [19].

AST, ALT, and CRP levels were found to be elevated in 27.6%, 21.6%, and 69.6% of the patients, respectively, and leukopenia (21.4%), thrombocytopenia (23%), and anemia (70%) in the study by Guler et al. [20]. 37% of patients were found to have hepatosplenomegaly on ultrasound, consistent with findings from a similar study done by Shi et al. [18].

Limitations

Only 77 cases could be included in the study. Not all the patients had all the laboratory tests done. Correlations were only weakly positive.

CONCLUSION

The most common clinical presentation of brucellosis was fever, arthralgia, abdominal pain, and headache. Elevated levels of CRP, procalcitonin, NLR, SGOT, and SGPT with thrombocytopenia and decreased levels of MPV were seen. A positive and significant correlation of CRP with NLR and PLR was also seen. Our study focused on the different clinical presentations and laboratory findings of brucellosis and will help give a better understanding and outline during brucellosis case diagnosis and management, in a more prompt manner.

CLINICAL PRACTICE

Clinicopathological evaluation of Moyamoya disease. Case report and review of literature

Nicolae O. Pop[1,2], Dana C. Zaha[3], Carmen Pantiș[1,2], Florina Mekeres[2]

Abstract: *Moyamoya disease is a rare affliction, which progressively affects cerebral arteries, more frequently those in the circle of Willis and the internal carotid arteries. This condition has a genetic component, but the cause of the disease is unknown. It usually affects children but can affect adults as well, representing a health issue due to its mortality. Not in a few cases, Moyamoya disease has been difficult to recognize as a cause of ischemic or hemorrhagic strokes. In this article, we present the case of a young patient, with a medical history of cerebral hemorrhage, which was diagnosed with Moyamoya disease after clinical and cerebral angiographic corroboration in a specialized vascular center. The patient entered the Emergency Receiving Unit with a sudden comatose state. Paraclinical tests revealed massive intraparenchymal hemorrhage, with movement in the medial line and ventricular flooding.*

Keywords: *Moyamoya disease, stroke, cerebral death*

INTRODUCTION

Moyamoya disease is a rare progressive blood vessel disease characterized by progressive stenosis of cerebral arteries, more frequently those in the circle of Willis and the internal carotid arteries. A collateral blood flow is formed around the blocked arteries to compensate for the lack of blood flow, but those collateral vessels are small and fragile, thus increasing the risk of bleeding, aneurysm and thrombosis [1].

The name of Moyamoya disease comes from the Japanese language, where it means "cloud of smoke". This disease was discovered in 1957 as an internal carotid artery hypoplasia of the tunica intima [2].

This condition has a genetic component, but the cause of the disease is unknown. Patients may present chorea, headache, seizures, or cognitive impairment expression of transient ischemic attacks or ischemic stroke and a large proportion of patients, mostly adults presenting with intracerebral hemorrhage. Two age peaks are recognized: one during childhood and one in young adults [1, 3]. In most regions, women are more frequently affected than men [3].

Although Moyamoya is a vascular disease, it is associated with other medical conditions like autoimmune disease, Down syndrome, arteriosclerosis, neurofibromatosis type 1 or other multiple tumors developing in the spinal cord [4, 5, 6].

In this article we present the case of a young patient, with a medical history of cerebral hemorrhage, who was diagnosed with Moyamoya disease after clinical and cerebral angiographic corroboration in a specialized vascular center and we review the literature on this disease.

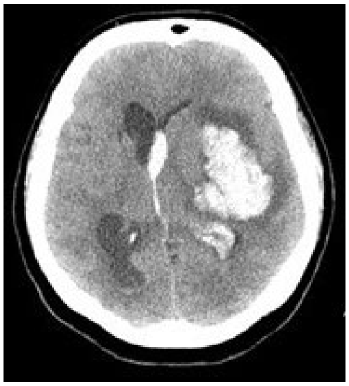
CASE PRESENTATION

We present the case of a patient aged 39, from an urban environment, known with having a medical history of cerebral hemorrhage in the previous year (twice in 6 months). The patient was investigated in a specialized vascular center in western Romania, where she was diagnosed with Moyamoya disease and was recommended a course of treatment. She is brought into the Emergency Clinical County Hospital in Oradea, Romania, with a sudden comatose state which had come on several hours before. On physical examination, neurological testing reveals asymmetric mydriasis, bilateral flexion in the plantar cutaneous reflex, symmetrical dropping of the arms and feet on the bed and a Glasgow score of 3. Other examinations (skin, extremities, abdomen, musculoskeletal system) were within normal limits.

A cranial CT scan shows massive localized hemorrhage in the left temporoparietal region, of 5.6/4/1 cm, with ventricular flooding in the third and lateral ventricles and mass effect with movement in medial line of 8 cm (Figure 1).

Figure 1: Cranial CT image shows the hemorrhagic accumulation with fresh blood; intraparenchymatous temporo-parietal densities with 5.6/4.1 cm axial diameters; slight perilesional edema, ventricular flooding in the bilateral lateral and third ventricles, and mass effect, the median line is shifted to the right by approximately 8 cm.



Laboratory results on admission showed hydro-mineral imbalance (hypokalemia and hypomagnesemia), which were corrected and remained within normal limits for the short duration of the patient's hospital visit. Complete blood cell count and examination of the peripheral smear showed normocytic anemia with normal leukocyte and platelet counts. Coagulation tests (D dimer, fibrinogen, partial thromboplastin time, prothrombin time, and thrombin time) were within normal limits.

The patient is then transferred to the Intensive Care Unit, where she receives orotracheal intubation and mechanical ventilation. Depletive and neurotrophic cerebral treatment is instituted, along with antibiotic therapy and acid-base and electrolytic balancing. The neurological state of the patient remains unchanged, with a Glasgow score of 3, fixed bilateral mydriasis and no cerebral reflexes. A control cranial CT scan is undertaken within another 48 hours, which shows the same collection of temporoparietal hemorrhage and no other modifications. The lateral ventricles have increased in size compared to the previous CT scan, with erased subarachnoid spaces (Figure 2). The suspicion of cerebral death is raised. After 72 hours, the suspicion of cerebral death was raised and the protocol in declaring cerebral death is followed, which is then confirmed by 2 EEG's, 2 apnea tests, ICU doctor, neurologist, neurosurgical assessment (Figure 3).

Figure 2: Cranial CT Image: the temporal-parietal intraparenchymal massive hemorrhagic left collection with ventricular intrusion in the right-side ventricle and ventricle 3 and relatively unchanged mass effect. The lateral ventricles have increased in dimension compared to the previous examination, bilaterally. Deleted subarachnoid spaces. Hypodensity of the cerebral parenchyma with deletion of the differentiation between the white subset and the newly developed gray substance which may suggest hypoxic ischaemia.

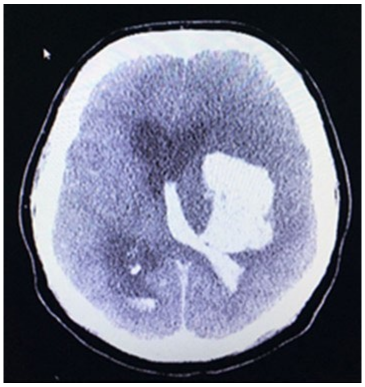


Figure 3: Evolution of patient

Day 1	- First hours, Glasgow 3 points - Emergency CT - Mass effect, with movements in medial line and compression of III and lateral ventricles
Day 3	- Glasgow 3 points - State of patient remains unmodified
Day 4	- Control CT - no modifications - Interclinical consultations for declaring cerebral death - Declared cerebrally dead

In the case we presented, the patient suffered a profound left cerebral vascular hemorrhagic accident, with three ventricular flooding and mass effect, as well as movement in the medial line by 8 cm, which made her comatose. Despite proper treatment, no signs of improvement were recorded. The family grants permission for transplant and investigations begin to facilitate organ transplantation. In the subsequent necrotic examination, a massive 7/6/3 intraparenchymal hemorrhage is observed, with erased channels and flattened circumvolutions, as well as reddish cerebrospinal fluid.

DISCUSSIONS

Moyamoya disease is a rare pathology, but its seriousness needs to make us aware of the risks that can appear. This disease is a medical problem from a variety of standpoints because it can appear in both children and adults, it progressively affects cerebral arteries through stenosis and occlusion and can lead to cerebral vascular accidents or repetitive transient ischemic attacks, which can kill the patient by themselves. Usually, children present symptoms attributed to slowly progressive cerebral hypoperfusion and repetitive ischemic symptoms, while adults have hemorrhagic or ischemic events [7-8].

The cause of Moyamoya disease is unknown, but it is believed that there is a genetic component involved [9]. According to some studies, this disease could be autosomal dominant, with incomplete penetration, depending on age and genomic factors [10]. Another study shows that the RNF213 gene is the main gene associated with Moyamoya disease [11]. In some studies, arterial stenosis was found to occur in not only the intracranial arteries but also renal, pulmonary, coronary, and pancreatic arteries. Renal artery stenosis is the most frequently reported associated with Moyamoya disease and the consequence is renovascular hypertension [12].

The walls of blood vessels have three layers in their structure: tunica intima, media and adventitia. From a morpho-pathological point of view, Moyamoya disease is characterized by the thickening of the tunica intima in internal carotid arteries bilaterally, which, at this level, can contain lipid deposits. The most frequently affected arteries are the anterior, middle and posterior cerebral arteries, which form the circle of Willis and can present with different degrees of stenosis and occlusion because of thickening in the tunica intima, curling in the internal elastic lamina and thinning of the tunica media.

The transversal sectioning of a basal artery in a patient with Moyamoya disease, with hematoxylin-eosin staining shows fibrosis and thickening of the tunica intima and proliferation of the smooth muscle cells (white arrows), as well as the folding and chronic contraction of the internal elastic lamina (blue arrows) and absence of inflammatory or atherosclerotic changes [13].

The incidence of the disease is greater in children around the age of five and adults around the age of 40. The condition is more frequent in women than in men, with a higher incidence in Asian population and a lower one in the European population. Women can present with transient ischemic attacks or cerebral hemorrhages in their medical history, or they can be asymptomatic. The recurrence in cerebral vascular accidents can be higher in these patients [14]. Clinically, patients with Moyamoya disease may present seizures, transient ischemic attacks, ischemic and hemorrhagic strokes. Headache, speech disturbances, visual deficits, intellectual deterioration, cranial nerve paralysis can also be seen in both children and adults. Mental retardation can be seen in children having Moyamoya disease.

Moyamoya disease is an important diagnosis to consider in children or young adults presenting stroke. Cerebrospinal fluid results of a lumbar puncture or electro-encephalography can be abnormal but are usually nonspecific. This pathology can be most frequently diagnosed in a quick fashion by using modern cerebral imaging methods such as an angio-CT, angio-MRI or 3D-DSA (rotational digital subtraction angiography), in a disease that is sometimes asymptomatic. Knowing all the radiological signs have a major influence on placing early and correct diagnosis, which can lead to prompt treatment and a possible increase in life expectancy in these patients.

Unfortunately, the therapeutic options are limited or inappropriate. Treatment in the acute phase is symptomatic for maintaining cerebro-vascular perfusion. Anticoagulant and antiplatelet agents, corticosteroids have shown no remarkable benefit. Surgical treatment procedures have been used to manage the hemorrhagic and ischemic consequences of Moyamoya disease to restore and maintain adequate cerebral perfusion, but there are serious adverse effects including cerebrovascular infarct or hemorrhage, motor or sensory dysfunction, cognitive decline, and death [15].

CONCLUSION

This pathology needs to be taken seriously because it presents a significant risk factor in creating cerebral vascular accidents, both ischemic and hemorrhagic, in young adults. Surgery can be beneficial, particularly if the diagnosis of moyamoya disease is made early. In patients with a history of cerebral accidents, angio-CT or angio-MRI and/or obtaining a protein RNF213 dosage would be recommendedto confirm or exclude Moyamoya disease in its early stages and institute proper specialized treatment.

Cloning and surface expression of engineered enzyme of organophosphorus hydrolase in E. coli and evaluation of its function

Hossein Ashiani[1], Gholamreza Farnoosh[2], Monireh Movahedi[1], Rezvan Seidmoradi[2]

Abstract: *Nowadays, the chemical compounds of organophosphate cause biological contamination due to their presence in the environment and production of metabolites, which endanger the health of humans and organisms. Thus, it is crucial to use a safe method to eliminate the contamination of these compounds. The objective of the present study was cloning and surface expression of the engineered enzyme of organophosphorus hydrolase in E. coli and comparing its function with the non-engineered enzyme. The present study aimed at improving the function of the organophosphorus hydrolase enzyme by expressing this enzyme along with Ice nucleation protein (INP) on the surface of bacterial cells. For this purpose, the OPH enzyme coding sequence was cloned in the pET28a-InaV-N plasmid and sent into E. coli, the strain of BL21 (DE3) and protein expression was evaluated at 37° C after 16 hours of induction. To examine the site of expression of the recombinant protein, cell components (cytoplasm, inner membrane, and outer membrane) were separated and the results were analyzed by using SDS-PAGE. The results revealed that OPH enzyme protein was presented as a protein fusion with a molecular weight of 58 KDa next to the INP anchor on the surface of the outer membrane of the cell. The specific activity of the resulting protein was calculated at 3828.8 U/mg after incubation of this enzyme in the vicinity of the substrate at 37° C. based on the results of the present study, it seems that the expression of engineered enzyme and its presentation on the cell surface is an achievement in using the cell as a degrading agent of organophosphate toxins and eliminating the costs of downstream processes such as purification and refolding of protein.*

Keywords: *clone, expression, engineered enzyme of organophosphorus hydrolase, E. coli, function*

INTRODUCTION

Following developments made in a recent century in the chemical synthesis of materials, new compounds have been made, some of which are toxic. Releasing of toxic compounds into the environment such as pesticides, insecticides, solvents, explosives, and dyes in industrial and agricultural applications has increased over the last decade [1]. One of these synthetic compounds is organophosphate compounds that are used in pesticides, insecticides, and neurochemical agents. These compounds have three phosphoester bonds, so they are also called phosphotriester. Phosphorus is attached to oxygen P = O or sulfur P = S by a double bond. Paraoxon, parathion, and diazinon are considered important pesticides and insecticides made from organophosphate compounds [2]. War nerve agents include G-type and V-type. It should be noted that V agents are much more toxic than G agents. The sudden release or poor management of pesticide and insecticide residues has contaminated the soil and groundwater in the region. Also, residues of nerve agents after wars can have devastating effects on the environment

and people. These compounds inactivate a large family of serine hydrolase enzymes (lipases and esterases) [3].

Acetylcholinesterase is one of the most important enzymes inactivated by these compounds, leading to the accumulation of acetylcholine in the nerve synapse and the continuation of nerve stimulation, and muscle dysfunction and impairment in the respiratory system respiratory failure, which results in coma and eventually death. Thus, it is essential to develop bioremediation technology to facilitate the degradation of organophosphate contaminants [4].

At present, most chemical and physical methods such as heat, superoxidase, carbon dioxide, etc. are used to remove contamination from organophosphate compounds, but they are associated with many shortcomings and disadvantages since they are often toxic, allergenic, corrosive, non-proprietary, and harmful to the environment [5]. Thus, safe technology is required to hydrolyze toxic compounds [5]. One of the useful methods for degrading the organophosphate compounds is the use of bacterial strains with enzymes that degrade these compounds with a wide substrate range.

Enzymes that as biocatalysts can degrade organophosphate compounds include organophosphorus hydrolase (OPH) derived from Pseudomonas diminuta and species of Flavobacterium, organophosphorus acid anhydrolase (OPAA) obtained from Alteromonas, and diisopropyl-phosphatase obtained from fish called Loligo vulgaris [6]. Expression of these enzymes in other hosts, including E. coli as recombinant, is one of the suitable methods for its production. OPH enzyme is present in Flavobacterium ATCC 75512 and P. diminuta.

The natural substrate for organophosphorus hydrolase is not known. This enzyme is a homodimer with a molecular weight of 72 kDa [7]. OPH can hydrolyze phosphotriester P-O bond in paraoxon, phosphonofluoride (P-F) bonds in DFP, sarin, and soman, phosphorothioate bond (P-S) in VX, and phosphoro amido cyanide (P-CN) bond in Tabun. The speed of OPH enzyme function is very high for a substrate with P-O and P-S bonds.

OPH is the only enzyme known for the degradation of both paraoxon and V-type war agents [8]. In a previous study, an engineered sample of this enzyme (creating a disulfide bridge to increase stability) was produced in the cytoplasm of E. coli. Despite changes in expression conditions, the enzyme was produced as an air inclusion and underwent difficult stages of unfolding and refolding [9].

In the present study, to solve this problem and express the enzyme in solution, by designing and synthesizing the anchor, the production of the desired enzyme was done as surface expression.

For this purpose, bioinformatics studies to design the best anchor were first considered, and then cloning, expressing, and finally measuring enzyme activity were performed.

MATERIALS AND METHODS

Preparation of materials required

Ecoli BL21 (DE3 (Novagen), pET32a (Biomatik), pET28-InaV-(Laboratory of Baqiyatallah University of Medical Sciences), LB-Agar and LB-Broth (Quelab), Yeast and Tryptone (Merck), Ampicillin, Kanamycin, Calcium chloride, XhoI, SacI (Restriction endonuclease), Agarose, DNA Safe Stain, Boric acid, Bromophenol Blue, 2-Mercaptoethanol, Taq DNA Polymerase, PFU DNA Polymerase, DNA Ladder-1Kb (# DM3200), T_4 DNA Ligase, Loading Dye, Ethanol 96%, Plasmid Extraction Kit, Fragment DNA Purification, Sodium dodecyl sulfate, Tris Base, Glycine, Glycerol, Coomassie Brilliant Blue G250, Glacial Acetic Acid, Tetramethylethylene-diamine, Isopropyl-β-thiogalactopyranoside, Acidleryed, B acrylamide Ethylenediaminetetraacetic acid, Triton X-100, Phenylmethanesulfonylfluoride, ammonium persulfate, Lysozyme, NaCl, Sucrose, and Urea (Sigma) were purchased.

pET28a-InaV-N plasmid

the pET system is one of the most powerful systems available for cloning and expression of recombinant proteins by E. coli. One of these systems is the pET-28a (+) expression vector, which includes the T7 promoter.

The gene can be cloned in the pET expression system and E. coli BL21 (DE3) can be transformed by the recombinant vector and expressed as a result of inducing by isopropyl β-D-1-thiogalactopyranoside (IPTG). pET28a includes an antibiotic marker of kanamycin. This plasmid has been used in previous studies and contains an anchor called InaV-N.

Figure 1 illustrates an image of this plasmid [10].

pET32a-OPH Plasmid

This plasmid has a T7 promoter for high protein expression and due to having a Thioredoxin tag sequence; it leads to secretion of the produced protein and has the antibiotic marker ampicillin.

This plasmid was used in a previous study conducted by Farnoush et al. The sequence of this plasmid can be seen in Appendix 1.

Figure 2 provides an image of the pET32a plasmid [11].

Plasmid purification

Plasmid purification was performed from strains containing plasmid pET28a and pET32a based on the standard protocol of the kit manufacturer. In short, 3 ml of the 18-hour culture of the strains was centrifuged and the supernatant medium culture was completely removed. The precipitate of cells was dissolved in 200 μl of FAPD1 buffer, 200 μl of FAPD2 buffer, and 300 µl of FAPD3 buffer and centrifuged at 250,000 rpm for 5 minutes. The transparent supernatant was poured on the columns for the kit and the columns were washed twice with 400 and 700 µl of W1 and Wash buffer and 50 µl of EB buffer was poured on each column and the desired plasmids were collected by centrifugation after 5 minutes [12].

Evaluation of purified plasmids by observing on agarose gel

Agarose gel electrophoresis is a standard method for isolating and identifying DNA fragments. A certain percentage of agarose is dissolved in the TBE buffer and, when cooled, forms a substrate that acts as a molecular sieve to separate DNA fragments based on their size in an electric field.

Polymerase chain reaction

For OPH gene amplification, two direct and inverse primers were required. These two primers were designed based on the initial and final sequences of the OPH gene. The direct primer is the complement at the beginning of the gene and the reverse primer is the reverse complement of the end of the gene. To insert this gene into the pET28a plasmid between SacI and XhoI sites, the cutting site of these enzymes was designed on direct and inverse primers and the synthesis order was given to the desired company (Table 1) [13].

Table 1: Primers of gene encoding OPH enzyme

Primer name	Primer sequence

Reverse (p264)	5'_ CATCTCGAGGCTTGCACGCAGAGTC_3'

Amplification of gene encoding OPH

To amplify the gene encoding OPH enzyme, the polymerase chain reaction was performed using designed primers according to the values presented in Table 2. PCR solution was prepared in 0.2 ml microtubes. In this reaction, the used model is pET32a, which contains the OPH gene, and a negative control sample was prepared according to previous values without the pET32a plasmid.

The microtubes were placed inside a thermocycler and reaction was done according to the temperature program presented in Tables 3-5 (Table 2) [14].

Confirming plasmid transfer into bacteria

To confirm the process of transfer of recombinant pET28-InaV-N/OPH plasmid into bacteria, PCR was performed for colonies grown on a solid culture medium. For each colony, some amounts were inoculated in 30 µl of sterile distilled water. Then, 15 µl of it was taken in 1 ml of liquid culture medium.

The remaining 15 µl was placed at 94° C for 15 minutes and then centrifuged at 13000 rpm for 2 minutes so that the broken cells precipitate. Supernatant media were used as a template in the PCR reaction.

The PCR reaction was prepared according to the values presented in Table 3 and performed according to the program of Table 4 [15].

Enzymatic digestion

For cloning the OPH gene within the pET28a plasmid, both the amplified gene and the purified plasmid need to be cut using similar enzymes. It causes a complementary adhesive end on the gene and the plasmid and facilitates the binding of the gene to the plasmid.

Cutting both sides of the amplified gene was done using XhoI and SacI enzymes according to the values presented in Table 5.

The mentioned values were poured into 0.5 ml microtubes and placed in a thermoblock for 20 minutes at 37° C. Then, the microtube was incubated for 15 minutes at 65° C to inactivate the enzyme [16].

Cutting of plasmid pET28a using two enzymes of XhoI and SacI

The plasmid was cut according to the values of Table 3-10 by two enzymes of XhoI and SacI to linearize the pET28a-InaV-N plasmid and remove the previous fragment. The mentioned values were poured into a 0.5 ml microtube and placed in a thermoblock for 20 minutes at 37° C. Then, the microtube was incubated for 15 minutes at 65° C to inactivate the enzyme (Table 6) [17].

Confirming entry of OPH gene into plasmid pET28-InaV-N by enzymatic digestion

To confirm the performed process and ensure the presence of the gene in the plasmid pET28-InaV-N, the plasmid was cut using two enzymes of XhoI and SacI with the values listed in Table 7. The mentioned values were poured into a 0.5 ml microtube and placed in a thermoblock for 20 minutes at 37° C. Then, the microtube was incubated for 15 minutes at 65° C to inactivate the enzyme [18].

Extraction of cut fragments from agarose gel using Kiagen kit

After cutting the gene and plasmid, it is necessary to separate these fragments from other extra fragments in the solution and then bind them together in a binding reaction. For this purpose, the product obtained from enzymatic digestion of plasmid was first taken on agarose gel and then extracted from the gel according to the kit protocol. The cut gene fragment was separated from the small cut fragments with the same kit without being placed on the gel. The gene was then purified by the clean-up method [19].

OPH enzyme protein expression

Plasmid gene-binding product was transferred into susceptible bacterial cells by the electroporation method. The culture was performed from colonies containing OPH gene plasmid in 5 ml of 2XY culture medium. When the optical absorption of the culture medium at 600 nm reached 0.7, after removing 1 ml of culture medium as an induction-free control, the promoter was induced by adding IPTG with a final concentration of 1 mM, and with the control sample, it was placed in an incubator shaker at 37° C for 18 hours. After the mentioned time, 1 ml of induced and control bacterial culture was precipitated and after adding 60 µl of 8 M urea, 16 µl of them were combined with 4 µl of sample buffer and heated for 5 minutes loaded on polyacrylamide gel [20, 21].

Primary evaluation of enzyme activity expressed on the surface

To evaluate the activity of the enzyme present on the surface, a precipitate of enzyme-expressing cells was collected and after twice washing with Tris buffer, 980 µl of cells with OD = 1 was poured into the microtube and 10 µl of cobalt chloride ion was added and 10 µl of parathion toxin was incubated for 1 h at 37° C [22].

Confirming surface expression of the enzyme

To locate the protein expression in the recombinant strain, it is necessary to first separate the cell components and then examine the fractions.

For this purpose, 20 ml of an overnight culture of control and test samples after protein expression, and their centrifugation and precipitate were dissolved in the lubricating buffer after washing twice in Tris buffer, and after half an hour of incubation at room temperature, the cell wall was broken with the sonicator device (4 30-second cycles with 80 power) was broken.

Then, centrifugation was performed at 2000 rpm for 3 minutes to separate the unbroken cells, and their supernatant was re-centrifuged at 14000 rpm for one hour. After emptying the supernatant into separate falcons, the precipitates were dissolved in Tris buffer containing Triton X-100 and 0.01 mM $MgCl_2$ and incubated at ambient temperature for 30 minutes to separate the inner and outer membranes.

Then, centrifugation was n performed at 13000 rpm for one hour. At this stage, the supernatant contains the inner membrane and the precipitate contains the outer membrane and the proteins attached to it. 500 µl of Tris buffer was added to both precipitates and dissolved.

Sampling was performed from each stage and examined using SDS-PAGE [23].

Evaluation of the specific activity of the enzyme in cell fractions

To evaluate the enzyme activity of the expressed OPH protein, a 50 mM Tris buffer was prepared.

The reaction medium containing 970 µl of Tris buffer, 20 µl of the sample (cytoplasmic samples, inner membrane, and outer membrane), 10 µl of cobalt ion with a concentration of 0.1 mM and 10 µl of parathion toxin with a concentration of 5 mg/ml were prepared.

After incubation at 37° C, the optical absorption of the samples was read at 405 nm and the specific activity of the enzyme was calculated using the following formula [24]:

$$\text{U/ml enzyme activity} = \frac{\text{dilution coefficient}\times\text{reaction volume}\times\text{absorption at 405nm}}{\text{time}\times\text{enzyme value}\times\text{PNP degradation coefficient}} \times 10^6$$

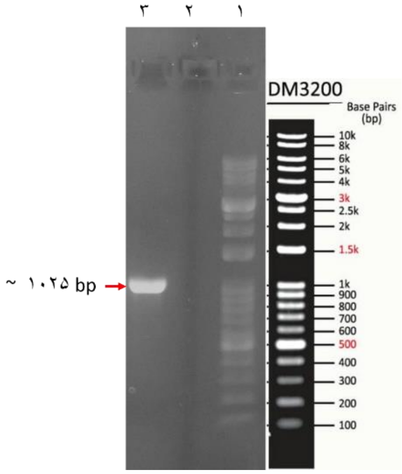
Reaction volume: 1 ml; Reaction time: 60 minutes; Dilution coefficient: 1; PNP degradation coefficient: 18000
Enzyme specific activity (U/mg) = normal activity (U/ml) / enzyme value (mg)

RESULTS

Amplification of OPH gene using PCR

In the first step, the OPH gene was amplified using p263 and p264 primers, and the PCR product was placed on agarose gel for confirmation. An observing band with a size of 1025 bp confirmed the amplification of the OPH gene. The OPH enzyme encoding gene is a 1008 bp sequence that, along with an enzyme site designed on primers, shows a length of about 1025 bp on the agarose gel (Figure 3).

Figure 3: OPH gene amplified by PCR.1- Marker # DM3200, DNA 1kb. 2. Negative control. 2. OPH amplified gene



Evaluation of fragments obtained from PET28a-InaV-N plasmid cutting and PCR product on agarose gel

Plasmid pET28a-InaV-N and OPH gene PCR products were cut using XhoI and SacI enzymes and some of each reaction was loaded on an agarose gel to confirm the enzymatic digestion process. The 1017 bp band observed on the gel displaying the OPH gene and the 5978 bp band relate to the cut plasmid pET-InaV-N (Figure 4).

Extraction of plasmid and gene from agarose gel using Kiagen kit

After performing the enzymatic digestion process and examining the accuracy of cuts made with agarose gel, the area related to the desired fragment was cut and removed from the gel with the help of a special kit. The results of this purification were evaluated on a gel (Figure 5) and its concentration was measured with a nanodrop. The concentration of purified gene and plasmid was determined to be 144 ng and 82 ng, respectively.

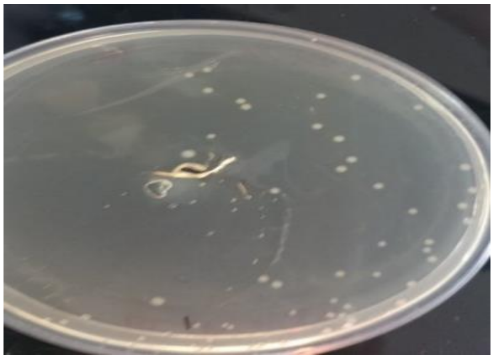
Transfer of recombinant pET28a-InaV-N / OPH plasmid into E.coli BL21 strain (DE3)

After proximity of the OPH gene and pET28a-InaV-N at the presence of the enzyme ligase, the recombinant plasmid was transferred into a bacterium by electroporation E. coli BL21 (DE3) and cultured on an agar medium containing the antibiotic kanamycin.

As shown in Figure 6, plasmid-containing colonies grew overnight.

Figure 6: Colonies obtained from pET28a-InaV-N / OPH transforming into E. coli BL21 strain (DE3).



Confirming of colonies containing recombinant plasmid pET28a-InaV-N/OPH by direct PCR method from colonies

To evaluate the accuracy of transfer of the recombinant plasmid within the bacterial strain, 12 colonies grown on the medium were used for PCR. Among the tested colonies, the 1025 bp band, which is amplified by the OPH gene, was observed only in colonies 10 and 14.

The gene-free sample was considered as negative control and the sample containing plasmid pET32a-OPH was considered as a positive control (Figure 7).

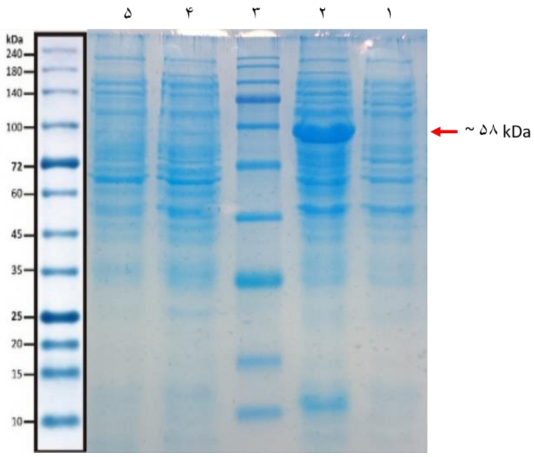
Induction of expression for two confirmed colonies

Two confirmed colonies were inoculated in 5 ml of culture medium and expression was induced after reaching OD600 of culture medium to 0.7. The results obtained on polyacrylamide gel are as follows. As shown in Figure 9, the

58 kDa band is observed only in one of the test samples and is not observed in-band control sample.

Figure 9: Expression of OPH enzyme in BL21 strain (DE3) at 37° C. 1 and 5 - samples of the negative control. 2 and 4 - Induced samples after 5 hours of incubation at the presence of IPTG inductor. 3 - Protein marker # PM1700



Evaluation of enzyme activity expressed on the surface

To evaluate the activity of the enzyme present on the surface at 37° C, 18 hours after adding IPTG, the precipitate of cells of test and control samples was collected and entered into the reaction medium. After one hour, the absorption of the reaction medium was read at 405 wavelengths and the enzyme activity was calculated. The samples include bacteria without the OPH gene and cytoplasmic enzyme-producing bacteria. As shown in Table 8, the activity of the enzyme expressed at the surface is lower than that of the enzyme produced as a solution in the cytoplasm.

Table 8: Comparison of enzyme activity expressed on the surface and sample expressed in the cytoplasm

Enzyme Activity (U/ml)	37^0 C
Gene without genes	0.74
Cytoplasmic expression	2.77
Superficial expression	7.67

Evaluation of the specific activity of OPH enzyme

After separating the cell components, the fractions related to each fraction of the cell were first examined by SDS-PAGE. Then, their activity was measured based on mentioned conditions, and the obtained data are shown in Figure 10. As shown in the figure, most of the activity is related to the outer membrane. It means the expression of enzymes on the surface of the outer membrane of the bacterium.

The specific activity of the OPH enzyme was estimated at 3828.8 U/mg using the formula mentioned in Figure 10 and Table 9.

DISCUSSIONS

Organophosphate compounds, including pesticides and neurochemicals, are very dangerous and insoluble in aqueous systems. Despite their high toxicity, organophosphate pesticides are still widely used to protect plants in agriculture. Due to the accumulation of these compounds in food products and water resources and its irreversible effects on human health and other organisms, it is essential to develop an advanced, appropriate, and cost-effective method to eliminate these compounds from the environment. Among the various physical, chemical, and biological methods, the use of natural strains as biodegraders has high importance. Strains such as Pseudomonas diminuta MG and Flavobacterium sp. ATCC 21881, which uses organophosphate molecules as food sources, can degrade a wide range of these compounds, including pesticides and neurochemical agents [25]. The degrading enzyme identified in these strains, called organophosphorus hydrolase (OPH), contains 336 amino acids and has a molecular weight of 36 kDa. The gene encoding this enzyme was used for expression in the cytoplasmic space of BL21 (DE3) bacterium after two mutations at sites 99 and 124 and altering two amino acids of threonine and glutamic acid to cysteine to create a disulfide bond, but its expression was mainly accumulated as protein masses in the cytoplasm and was dysfunctional and without proper structure [26, 27]. Thus, the bacterial cell must first be lysed and after extracting the accumulated proteins, they must be solubilized with a strong denaturator and the refolding process must be continued in the presence of appropriate stabilizers. All of these steps require much time and money, and finally, with the loss of a part of the protein, a protein is obtained that often does not regain its structure 100% and does not have good stability [28]. Another form of OPH enzyme expression is performed as periplasmic expression. In research carried out in 2015 by Latifi et al, the OPH enzyme encoding sequence in E. coli was synthesized and the OPH enzyme was expressed in the form of air inclusion using pET21a-opd and pET26b-opd in periplasmic space. Periplasmic expression of this enzyme also leads to limited production of this enzyme and requires complementary processes such as bacterial cell breakdown and protein extraction from the cell [25]. Besides the various methods proposed for the expression of recombinant proteins as a solution, including reducing the temperature, reducing the concentration of inducer, and using sequences that help solubilize the protein, the use of membrane anchors to provide protein on the bacterial cell surface is one of the most effective strategies used to express a wide range of proteins and has yielded promising results since molecule when attached to a matrix-like the cell surface is more accessible and much more stable than the free molecule and does not require long and costly purification steps [26, 27]. The use of natural integral proteins of the outer membrane as carriers is necessary for the goals of presentation on the surface. A variety of surface anchor motifs such as Lpp-OmpA, INP, and auto-transporters are used in this system due to their properties [31]. OPH enzyme expression in E.coli has been performed as a surface expression by various researchers. For example, in a study conducted by Richins et al in 1997, OPH enzyme expressed the OPH protein on the surface of E. coli using an Lpp-OmpA anchor system [32]. Shimazu et al in 2001 examined the expression of OPH protein by three anchors, including Inak-NC, InaV-NC, and Lpp-OmpA. The Inak anchor motif was derived from P. syringae KCTC 1832 and the InaV motif was derived from P. syringae INA [33]. Dong Kang et al in 2008 used only the second InaK amine to provide OPH on the surface [34]. In each of these studies, the OPH enzyme was expressed by different anchors on the cell surface. As a surface expression of OPH enzyme in previous studies in E. coli has resulted in the production of functional and highly stable proteins, and since the engineered OPH enzyme used in this study has been previously expressed in the cytoplasm due to its disulfide bond in the air inclusion and non-functional form, this sequence was re-expressed differently in E. coli in the form of surface expression using the InaV-N anchor. The results of investigating the activity of different parts of cell fractions showed that the fraction related to the outer membrane has the highest activity and has an activity more than twice as much as other cell fractions. Inav-N anchor not only can transfer OPH protein on the surface of bacteria but also has a positive effect on its activity.

CONCLUSIONS

The main objective of the present study was a surface expression and improving the efficiency of the engineered enzyme OPH (containing disulfide bridge) which was expressed in the previous study as air inclusion. The use of InaV-N anchors, which is one of the known anchors for surface expression, responded well to the desired enzyme and the enzyme could maintain its activity after surface expression. In a conclusion, this study could solve the problem of the insolubility of the protein, maintain its structure and its desirable activity, while surface expressing the engineered protein using the InaV-N anchor on E. coli bacteria.

Colorectal cancer epidemiology and risk factors

Diana Chetroiu[1,2], Corina S. Pop[1,2], Sorina Diaconu[1,2], Mircea Beuran[2,3]

Abstract: *Colorectal cancer is an important health problem, being the third most frequent cancer pathology both in men and women. Programmes have been developed to decrease CRC incidence and mortality, including primary prevention strategies focusing on population education regarding diet and physical activity and secondary prevention programmes such as screening. Modifiable risk factors are known to be diet, obesity, smoking, alcohol and read meat consumption. Non-modifiable risk factors are age, inflammatory bowel disease, genetic syndromes and family history of colorectal cancer.*

Keywords: *colorectal cancer, risk factors, genetic syndromes, Lynch syndrome, diet, obesity, diabetes*

Colorectal cancer is an important cause for mortality and morbidity all over the globe and recent data from the United States of America report it as the third most frequent cancer pathology both for women and men. [1]

According to American Cancer Society, the risk for developing colorectal cancer during lifetime is 1:23 for men and 1:15 for women. [2] In industrialised western countries, the lifetime risk for such malignant pathology is approximately 5%. [3]

World Health Organization reports approximately 1.9 million new cases every year. [4] Incidence and morality due to colorectal cancer increase with age, most of the cases being diagnosed around 70 years of age. [5] During last years, it has been reported an increasing in incidence with 1 % for people 50 to 64 years of age and by 2 % for people younger than 50 years. [6] Because of increasing life expectancy, people migration and changes in daily habits, it is expected that by 2035, there will be 2.4 million new colorectal cancer cases world wide. [5]

In Romania, the incidence of CRC is 10.1/100000 in men and 7.3/100000 in women. [4]

All over the world, strategies have been developed in order to reduce colorectal cancer incidence and mortality. These strategies cover primary prevention such as educational programmes for healthy life style and secondary prevention, such as screening programmes. [7, 8]

Regarding the risk factors involved in colorectal cancer pathogenesis, they can be divided into two major groups:

1. Non-modifiable risk factors: age, sex, personal history of adenomas, personal history on inflammatory bowel disease, family history of colorectal cancer or genetic syndromes

2. Modifiable risk factors: diet, physical activity, weigh gain, medication, alcohol consumption and smoking

1. Age is an important non-modifiable risk factor, as colorectal cancer risk starts to increase after the age of 40, and most of cancers are diagnosed after 50 years, with a

maximum of incidence between 60 and 70 years of age. [9] Latest reports show an increase in CRC incidence in 20-49 years of age persons and so it becomes one of 10 most frequent cancers for this group. [6, 10]

As for differences between sexes, it appears that colorectal cancer is more frequent in men that in women, regardless of the age group, with 4.4% risk precent in men and 4.1% in women. [11] There is an interesting discussion regarding the distribution of precursor lesions in men and women. In women, adenomas are more frequent in proximal colon while in men, adenomas have a distal grow pattern. [12] This information in useful in choosing the best method for screening both in men and in women. [13]

During lifetime, the risk of developing a tubular or villous colorectal adenoma is approximately 19%. [14] 95% of sporadic CRC develop from adenomas, as they are known to be precursor lesions. [15] Interestingly, not all adenomas evolve in colon cancer. Most of them will regress. It usually takes approximately 10 years for a polyp to transform in a malignant tumor. [16] So there is an opportunity window in order to discover precursor lesions through screening. This is why people with personal history of adenomas should be monitored with colonoscopy, in order to decrease the risk of developing colon cancer. [17] Also, an important topic to debate in this case is the role of modifiable risk factors that maybe influence in a positive manner by reversing the process of transformation from adenoma to carcinoma. If it is really so, it would be quite difficult to demonstrate it.

Another important risk factor for developing colorectal cancer is the personal history of inflammatory bowel disease, meaning Crohn disease and ulcerative colitis. The severity of endoscopic and histologic inflammation, the duration and the extent of colorectal lesions are important elements that increase the risks of neoplasia. [18, 19, 20] Patients with inflammatory bowel disease have a sixth time higher risk of developing colorectal cancer, comparing to normal population, and the risk is even higher for those with extensive colitis. [21]

Although approximately 75% - 80% of colorectal cancers are sporadic forms, the rest of 20-25% are diagnosed in persons with familial history of colorectal cancer [22] especially in first degree relatives of patients with colorectal cancer diagnosed before 60 years of age [23]. In these familial cases, genetic factors and life style work together.

Genetic syndromes are involved in 5-10% of diagnosed colorectal cancer. The best known and studied genetic syndromes are:

- Lynch syndrome - hereditary non-polyposis colon cancer (HNPCC)

- Familial adenomatous polyposis (FAP) with its subtypes: attenuated FAP (AFAP), Gardner syndrome and Turcot syndrome

- MUTYH - associated polyposis (MAP)

- Peutz-Jeghers syndrome (PJS)

Lynch syndromes is the most common inherited CRC syndromes as it accounts for approximately 2-4% of cases. [24] The risk of developing colorectal cancer during lifetime is about 70-80% and the median age at diagnosis is usually around 40 years of age. [25] This hereditary syndromes is causes by a mutation detected in the genes responsible for DNA repair (for example MLH1, MSH2 or MSH6). People with this condition can also develop gastric, pancreatic or uterine cancers. [26]

In the case of familial adenomatous polyposis (FAP), the risks of CRC cancer is given by the germinal mutation of APC gene from chromosome 5q21. [27] In this case, the patient is diagnosed with hundreds or even thousands of polyps in colon and rectum having a major risk of transformation in colon or rectal cancer before the age of 20 years. [28] This disease is diagnosed in less than 1% of population. [27]

People with AFAP are diagnosed with less than 100 polyps during colonoscopy and the higher risk of colorectal cancer is around the age of 40. [29] Regarding the other attenuated forms of FAP, the high risk for colorectal cancer remains and is associated with other forms of non-cancerous tumours of skin, bones or soft tissue as in Gardner syndrome or with medulloblastoma as in Turcot syndromes. [24, 28]

In MUTHY-associated polyposis, the risk of cancer is also reported at a young age. In this case, colon polyps appear because of MUTHY gene mutation, a gene that is involved in "proofreading" the DNA. People with this condition also have an increased risk of thyroid and other gastrointestinal cancers. [29]

Peutz-Jeghers syndrome appear because of STK11gene mutation. Is a very rare syndrome. It is associated with increased risk of hamartomas in digestive tract and breast, ovary and pancreatic cancer, beside colon cancer. [30]

2. Taking into consideration that 75-80% of colon cancer are sporadic forms, it is considered that environmental, dietary, cultural, educational and social factors play an important role in this disease occurrence and, by educational programmes, it is a preventable cancer. This statement is supported by population studies focused on health of migrants and their children. It was observed that in migrants that came from low incidence colorectal cancer countries,

the incidence of this neoplasia starts to increase during lifetime and their children have the same incidence of colorectal cancer as the people in the adoptive country [31, 32]. Also, the incidence is higher in urban area than in rural area. [32]

For many years, a large number of studies and meta-analysis tried to pinpoint the risk factors for colorectal cancer. The conclusion was that high consumption of read meat or processed meat, heavy alcohol consumption and smoking, high mass index and lack of physical activity are clear factor that can raise the risk ok colon cancer. [33-35] Data show that by consuming 5 portions of red meat per week, one can have a 13% increased risk of developing colon cancer. [28] In contrast with this data, fruit and vegetables can reduce the risk of colorectal cancer by 15% if consumed for as many as 3 portions per day. [36]

Alcohol and smoking are considered to produce inflammatory damage of normal colon mucosa, leading to formation of polyps. Although the exact mechanism by which alcohol affects colorectal mucosa is not completely understood, in the case of cigarette, it is considered that carcinogens are the ones to be incriminated in this process.[37] Studies showed that there is a 3 fold higher risk for smokers to develop colon polyps. [38]

Weight gain and maintaining a high body mass index can promote inflammatory state through inflammatory cytokines and adipokines. [39] This process favours angiogenesis and colon carcinogenesis. In this case, the protective role of NSAID, in reducing inflammation, especially Aspirin is quite easily to be understood. [40]

The EPIC study demonstrated that by adopting a healthy life style, meaning weight control, sustained physical activity, lack of smoking, low consumption of alcohol and read meat can actually decrease the risk of developing colorectal cancer. [41]

Given the important role of diet, constant exercise and maintaining a normal body index in preventing colorectal cancer and consistent with EPIC study results, World Cancer Research Fund/American Institute of Cancer Research (WCRF/AICR listed a number of recommendations for healthy population and also for colorectal cancer survivors [42] A summary of these recommendations is:

- Body mass index - one should maintain as thin as possible without becoming underweight
- Physical activity - at least 30 minutes per day
- Restrict as much as possible sugary drinks
- Consume vegetables and fruits
- Limit red meat and avoid processed one
- Limit alcohol intake
- Limit salt consumption
- It is preferred to have all nutrients mostly from diet and less from supplements
- Breastfeeding for women

An interesting discussion is linked to patients with diabetes. It appears that they have a higher risk of colon cancer, although this can be related to increased body mass and sedentary, studies demonstrated that even with correct diet and physical activity, they still have an increased risk of CRC than that of general population. [34]

Also, the use of insulin in the treatment of diabetes it appears to be related to a higher risk of CRC diagnosis and a worst prognosis than the patients with diabetes treated with metformin. [43]

Much discussion takes place in the last 10 years regarding microbiota role in colorectal cancer carcinogenesis. It is certain that in patients with colorectal cancer, colonic dysbiosis is reported. Several bacterial species might play a role in CRC such as Streptococcus bovis, Enterococcus faecalis, Fusobacterium spp or Bacteroides fragilis [44-46] Pro-carcinogenic results of the presence of these micro-organisms are described to be: genotoxicity, inflammation, oxidative stress, host defence regulation [47] More studies are in progress analysing the correlation between microbiota composition changes and molecular pathways of colorectal cancer

CONCLUSIONS

Taking into account all the modifiable risk factors, the need for primary prevention programmes is clear in order to decrease the burden of colorectal cancer incidence.World Health Organisation listed recommendations to be taken into consideration by general population regarding diet, physical activity and weight control.

Regarding non-modifiable risk factors, the secondary prevention programmes must be considered crucial for people with family history of colon cancer or for those diagnosed with inherited familial syndromes.

Common artifacts in myocardial perfusion imaging

Raluca Mititelu[1], Silviu Stanciu[2,3], Catalin Mazilu[1], Teodora Mititelu[4], Letitia Mititelu[4], Alina M. Gherman[1]

Abstract: *Myocardial perfusion imaging (MPI) is an important non-invasive imaging method, which allows the assessment of perfusion in the cells of the myocardial wall. The images are obtained after administration of a radiopharmaceutical at rest and/or after maximal stress (physical effort or pharmaceutical stress). Infarction areas or scars will not show any uptake of the radiopharmaceutical, neither in rest nor at stress (fixed defects), while the ischemic area will show reduced uptake at stress with recovery to normal perfusion at rest (reversible defects).*

MPI is a complex technique and it requires an experienced team to foresee, avoid, correct or minimize the artifacts that might appear in all the phases of the study

In this paper, we will present the most important categories of artifacts, based on the category of problem where they were generated. We will also present some solutions for limiting these artifacts or for recognizing and minimizing their effect for those which cannot be avoided.

Keywords: *myocardial perfusion imaging, artifacts, a non-invasive imaging method*

Myocardial perfusion imaging (MPI) is an important non-invasive imaging method, which allows the assessment of perfusion in the cells of the myocardial wall, after administration of a small quantity of radioactive material – a radiopharmaceutical. MPI is an imaging modality that helps identify the differences between myocardial perfusion at rest and stress (Figure 1).

The most used radiopharmaceuticals in MPI are 99mTc-MIBI and 99mTc-tetrofosmin as they distribute to the myocardial tissue proportional to the blood flow thus to the cell perfusion. The radiopharmaceutical is intravenously administered to the patient at rest and/or after a maximal effort – either physical effort or pharmaceutic stress. The pharmaceutical stress is achieved by administering substances that enhance blood flow in the healthy myocardium; this will lead to consequently decrease in variable degrees in ischemic territories. Therefore, the infarction areas or scars will not show any uptake of the radiopharmaceutical, neither in rest nor at stress (fixed defects), while the ischemic area will show reduced uptake at stress with recovery to normal perfusion at rest (reversible defects).

After the administration of the radiopharmaceutical, the patient is placed inside the gamma camera (SPECT scanner). With the rotation of the system detector around the patient, a series of planar images are obtained; these images (acquisition raw data) will later be used to obtain reconstructed views in the three-section plans of the heart: short axis, long horizontal axis, and long vertical axis. Two data sets of images are obtained in this way, illustrating

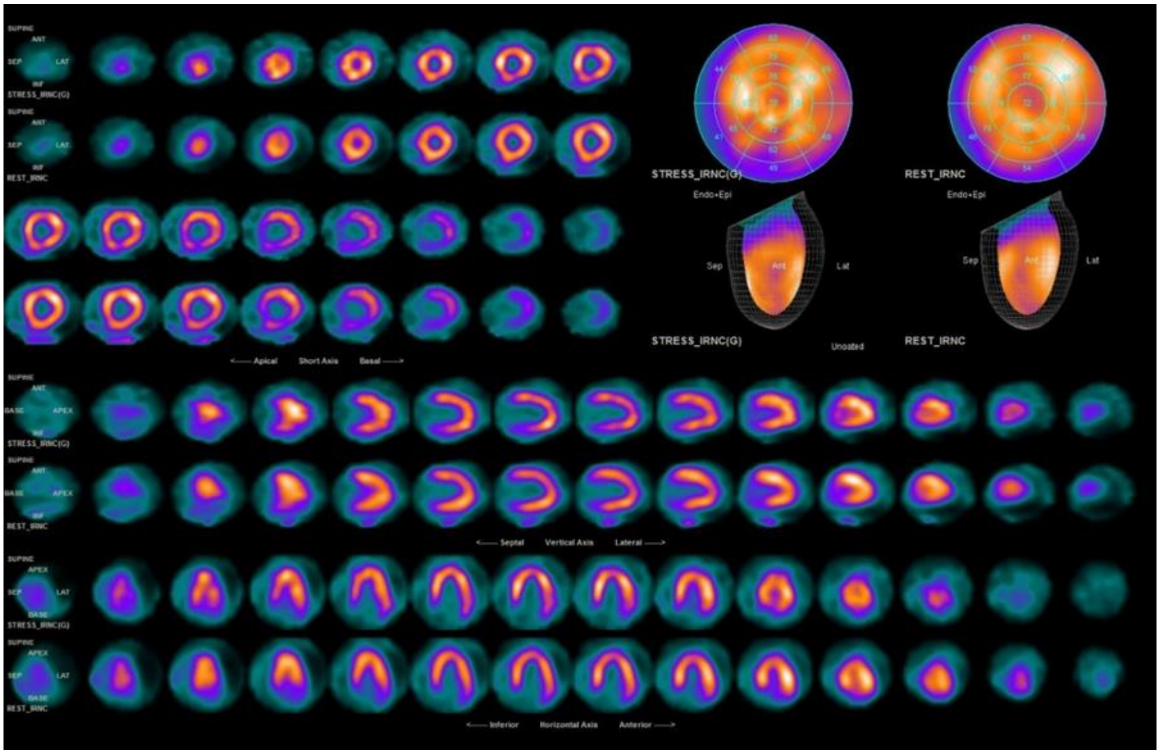
myocardial perfusion at rest and stress.

Figure 1: MPI, 99mTc-tetrofosmin, one day protocol (stress-rest). Reversible defect in inferior wall



Modern systems allow image acquisition, synchronous with the ECG, resulting in a reconstruction that will provide information about the myocardial dynamic parameters like volumes (telesystolic and telediastolic), the systolic function, and systolic thickening.

In normal conditions, the myocardium of the right ventricle will not be seen on MPI. It can however show some degree of uptake in conditions that associate its hypertrophy.

MPI is a complex technique and it requires an experienced team to foresee, avoid, correct or minimize the artifacts that might appear in all the phases of the study.
Many types of artifacts can interfere with the MPI/ Most important of these artifacts can be classified according to the category of problem where they were generated (Table 1):
- problems related to the preparation of the investigation
- technical aspects involving scanning, processing, and the work protocol
- patient-related aspects: moving during the scan, attenuation of photons within the body, associated pathologies, intestinal radioactivity.

Problems within the preparation of the investigation

The investigation must be well prepared because neglecting some of the steps might lead to major artifacts or even compromise the study.

For the stress study, the patient is advised to stop medication containing beta-blocker or any other treatment that might prevent reaching the maximum heart rate [1]. Normally, the use of pharmacological stress is preferred for patients who can't perform physical effort that would lead to reaching a minimum of 80% of the maximum heart rate.

During the preparation of the radiopharmaceutical, it is necessary to follow a strict protocol to fulfill the radioprotection standards but also to avoid a higher percentage of free 99mTc (pertechnetate – 99mTcO$_4$). Free 99mTc - 99mTcO$_4$ has another physiological distribution compared to the 99m-Tc-MIBI/tetrofosmin. Furthermore, a higher free fraction will lead to a considerable shrinkage of the active doses.

The administered doses have to be sufficient and adjusted according to the patient's weight to obtain the awaited distribution, This is particularly important for one-day stress-rest studies that involve two injections. In this case for the second investigation is required a sufficient dose, because photons from the first administration might still be detected.

Table 1: Most common artifacts in MPI

Artifacts related to the investigation preparation)	Administering medication that limits the maximal heart rate at stress	
	Preparation of the radiopharmaceutical	
	Incorrect dose of administered radiopharmaceutical	
	The extravasation of substance during intravenous administration	
Artifacts due to technical issues	Equipment errors	Uniformity
		Rotation center
		Detector alignment
		Attenuation correction system
	Processing and postprocessing errors	Incorrect choice of section plans
		Choice of non-adapted filters
	Protocol errors	Non-compliance with the optimal post-injection acquisition time
		The short time between rest and stress studies (one-day protocol)
Patient-related artifacts	Movements during the scan	
	Photon attenuation within the body	Diaphragmatic attenuation
		Breast-induced attenuation
		Adipose-induced lateral defect in obese patients
	Associated pathologies	Left bundle branch block
		Arrhythmias
	Subdiaphragmatic Activity	
	Anatomical variations (apical thinness, shorter septum)	

The radiopharmaceutical is administered intravenously by trained medical personnel, avoiding extravasation.

Technical aspects involving scanning, processing, and the work protocol

Technical issues can be related to the scanning equipment (components of the scanner), image processing, or acquisition protocols.

The equipment requires daily check-up – both the gamma camera and the equipment required for measuring de radioactivity dose. There might be certain errors concerning the scanner's components that would lead to the appearance of artifacts and therefore to make the image interpretation more difficult.

Among the most frequent technical issues that can lead to image artifacts, we can name uniformity, misalignment of the rotation center, detector alignment, and desynchronized function of the attenuation correction system. All of these errors can be avoided or, at least, reduced by following a strict, periodical quality control protocol with systematic checking of the medical devices [1-3].

Processing of the acquisition raw data might be an important source of artifacts in the final images. Luckily, if the acquisition data were correctly obtained in a standard protocol – the processing procedure can be restarted and the artifacts corrected. The most frequent causes of artifact due to processing are related to incorrect filter application or mistakes in the reconstruction – heart orientation, choice of the section plans [4]. Processing errors can generate either false-positive or false-negative results.

Imaging acquisition at a shorter timespan after the administration of radiopharmaceutical than recommended might generate weaker statistics and faulty images. Additionally, for the one-day stress-rest protocol – the second investigation in a shorter timespan might considerably affect the quality of the study.

A good positioning within the scanner is required to get a full heart image.

Patient-related aspects

Artifacts resulting from patient movement during image acquisition might considerably influence the interpretation and in some cases even mimic a perfusion defect (false positive study).

The phenomenon of photon attenuation within the body is a common cause of artifacts. These are generally fixed defects visible both in rest and on stress images. Specifically, if there are no possibility of correcting the attenuation (e.g., through simultaneously transmission scanning as in CT) attenuation defects can be differentiated from real defects through gated SPECT. The territories which show attenuation defects will always present normal parietal kinetics [2, 5, 6]. Generally, there are three sources of soft tissues attenuation defects: the presence of big breast in women (anterior wall defects), diaphragm (especially in men – it determines false inferior wall defects), or in obese patients with important lateral adipose tissue (defects of the left ventricular lateral wall)

Some associated nonischemic pathologies can influence the appearance of the perfusion study. They are most commonly represented by arrhythmias and by the left bundle branch block.

Left bundle branch block can determine anteroseptal defect, either fixed or reversible, leading to a decrease in the specificity of MPI in this category of patients [4, 7, 8].

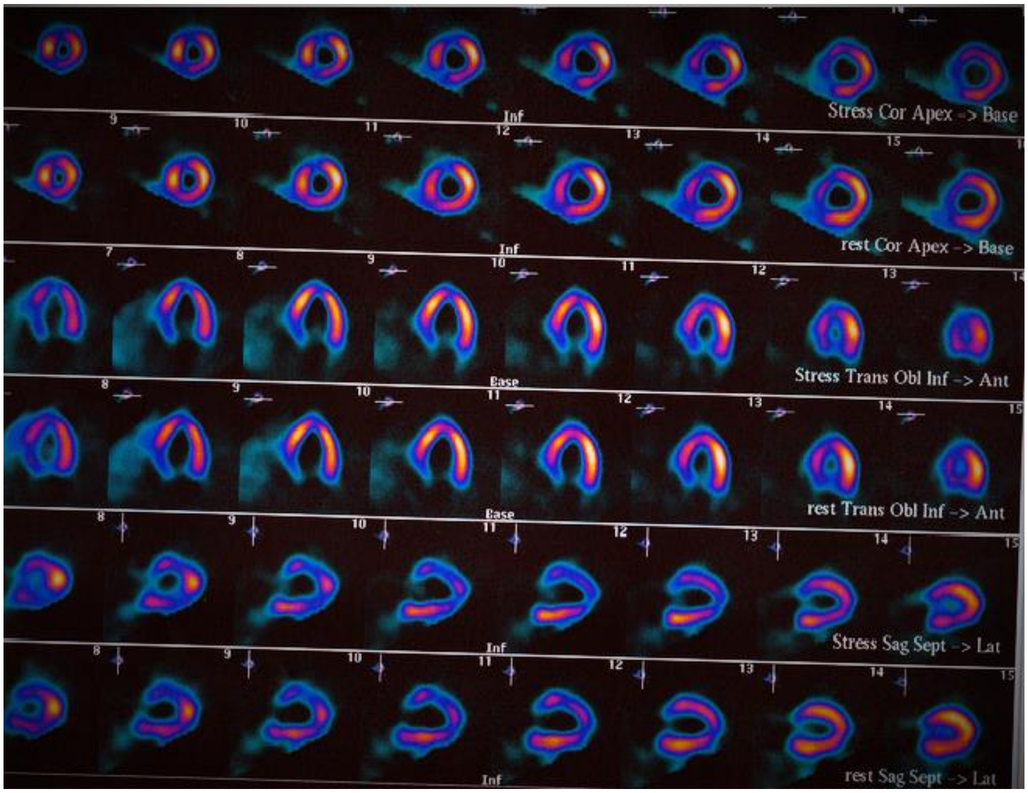
Other groups of pathologies that can influence and lead to artifacts are represented by arrhythmias, which might significantly influence ECG-gated studies.

Important subdiaphragmatic activity (hepatic or intestinal) is due to the excretion of the radiopharmaceutical through the hepatobiliary system. These phenomena can interfere with the radiopharmaceutical uptake on the inferior wall in two ways: (a) high uptake on the inferior wall (Compton effect) with the cover-up of a possible perfusion defect and (b) relative decrease of uptake on the inferior wall, next to the intestinal area of high uptake, a tributary to the use of reconstruction algorithms (false-positive results).

The subdiaphragmatic activity can be reduced through a low-intensity physical effort (resulting in a lower splenic activity), large quantities of fluids or even eating high-fat foods that might bias the radioactivity in the distal GI tract [5, 9].

Some anatomical variations might of course impact the visualization – e.g., the presence of a thin myocardial tissue layer at the apex might mimic a perfusion defect, as does a shorter sept (Figure 2).

Figure 2: MPI, 99mTc-tetrofosmin, one day protocole (stress-rest). Fix defect in apex (apexian thinning) and short septum



CONCLUSION

MPI represents a high-performance imaging modality that relates to advanced knowledge in pharmacology, pathology, and clinical cardiology combined with high-level technical aspects in medical devices and image processing systems. The role of a well-trained multidisciplinary team is mandatory for performing and interpreting the study. With the correct implementation of working protocols and the use of standardized methods, the presence of artifacts can be limited. However, there is several pitfall or artifacts that cannot be avoided due to particular conditions. In this case, it is important to recognize artifact changes with result in better accuracy of the procedure while maximizing the benefit of this imaging technique in routine clinical practice.

Comparative study on the independent learning activity of young people in the bachelor's and master's programs

Antonia I. Trifu[1], Radu V. Costea[2], Roxana T. Bejan[3]

Abstract: *During the late adolescence, it can be reached the highest level of mental operative functions and other intelligent human manifestations. Abstract mental operations can be done at this level: synthesis of syntheses, generalization of generalizations, abstraction of abstractions. Students go through many attempts to find which is their personal style of learning new materials, new contents. The study was conducted on a number of 31 participants. The group was divided into two subgroups: 16 students in the 5th year at Faculty of General Medicine and 15 master students in the second year at University of Sports, Sports Performance program. The used instrument consists of 21 questions (11 questions are about the individual studying process of the participants and 10 are about their beliefs about the teaching process of academics in courses), along with 4 more questions related to personal data. It is an opinion questionnaire. The teaching style of academics differs: those of Faculty of General Medicine are focusing on a lecture type style (75%), and University of Sports on an interactive style (67%). We discovered differences in the process of self-learning: between continuous and discontinuous style. For medical students, there was a longer distribution of the self-taught learning process; instead, University of Sports students organize their learning time in the last part of the semester. University of Sports students are more concerned with on the development and refinement of their personal practical skills, but also of the subjects they work with (kids or athletes), their goal being to accumulate their own experience as rich as possible from working with as many individuals and less to take from the experience of other colleagues. The coach-athlete/sports teacher-pupil relationship is more personalized and longer-lasting than the doctor-patient relationship.*

INTRODUCTION

1. Learning activity and its role in summative assessment

1.1. Learning activity for young people - generalities

During the adolescence period (considered between 14/15 and 20 years), the individual seeks his own identity and begins the stage of abstract thinking. Hayford [1] highlights the student period of 18/20-24/25 years as a prolonged adolescence. The young adult age is between 20-40 years and assumes that the most important aspects are the intellectual skills that will be used in professional life and the foundation of intimate and personal life.

Around the age of 17-18, the highest level of mental functioning and the manifestation of human intelligence is reached. The operations of thinking are fully liberated from the informational contents to which they were initially applied, they are generalized, they are transferred and they become formal. Thus, the second-degree operations are

Corresponding author: Antonia Ioana Trifu

[2] Department of General Surgery, „Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania
[3] Teaching Staff Training Department, The National University of Physical Education and Sports, Bucharest, Romania

successful: syntheses of syntheses, generalizations of generalizations, abstractions of abstractions.

Piaget describes the stage of concrete operations as ending around the age of 12-13 years old, when adolescents are able to perceive the constancy of objects in terms of transformations, regarding structure, volume, in a nutshell, the ability to understand the fact that objects are constant in relation to the notion of flexibility. After the age of 13, up to 17-18 years, the stage of formal operations is completed, when young people manage to think inferentially, including the possible, with the issuance of assumptions and the definition of specific pathways for each option seen separately. It defines the logic, the concepts of contradiction, certain grammatical structures of the “double negation” type, the detection of the grammatical concepts of circumstantiality and attributiveness and the optional-conditional, which could be seen differently. Also, an important role is played by the concept of “perceiving the absurd” or of the possibility to operate on the determinants, of the empty set, in the sense of superior mathematics.

During late adolescence, there is a strong conflict related to the balance between maturity and childhood, the balance between needs and how to meet them, due to the relationship between aspirations and possibilities and the conflict between dependence and independence.

Some authors [2] consider that adolescence is a period of confusion, but also a period of future projections that the adolescent makes. The desire for self-improvement appears, emotions and feelings are amplified, moral autonomy and self-awareness are developed, the adolescent has the feeling of independence. There are feelings of disagreement and rejection of ideas imposed by other people.

The period of youth, between 20-24 years [3] is considered a period of transition to adulthood. The acquisition of economic autonomy begins, leading to greater independence. Levinson [4] calls the period from 17 to 22 years - the period of young adulthood and considers that it is characterized by the coexistence of the adolescent and the young adult status. He considers that it is a period of transition dominated by the transition of the young man from the state of child-man to that of young man.

Young people begin to become autonomous, move away from the family environment, from the model imposed by their childhood, create their own social system and thus structure themselves as individuals and part of their generation. The aspirations, the ideal about the world and life, the value system begin to particularize and become constant, proper in the young person's life, giving coherence to his/her actions.

Learning is the main activity of young people. They have a very high capacity to assimilate information, to incorporate it. They also show an increased availability for this activity. The preoccupation for learning comes from an internal motive towards self-improvement, continuous development, search for existential meanings and senses. They are beginning to lose the importance of the school assessment, grading and ranking component, focusing on the activity of acquiring the necessary knowledge in the desired field. According to Erikson [5], the adult stage involves: amplifying social identity, employment and involvement in social life, intense feeling of love, the beginning of family life and the development of intimacy, the oscillation between isolation – intimacy - the tendency to link relationships with others groups.

Knowledge and, in general, the intellect has a wider notional area than the psychic process of memory. In turn, memorization is only the first part that defines memory as a high psychic function, the other two aspects being the preservation of information and updating (which can be in the form of recognition or reproduction). The intellect is the superior form to which the definition of the personality of young people accesses, this including the peaks of the "iceberg" represented by each function or psychic process. In the absence of memory, life would be a "ball of sensory impressions", structuring the continuity of the psyche leaving "gaps" in the network in which students submit their information. If we refer strictly to the psychic process of memorization, we can describe the concept of "buffer", in which many students run, more or less information, depending on individual abilities, some being those who learn early and cope with information exams stored in long-term memory, others having as a favorite profile the loading of the buffer (this being a capacity, an ability in itself) and having remarkable results with the information stored here. The persistence over time and the effectiveness of this type of long-term learning in relation to valid and valuable expression in the future profession is to be discussed.

The overall mental operations are developed and many specific algorithms are formed. The motivation for vocational learning is strong, especially practical work-related learning. Another important aspect is that learning becomes strongly selective, conscious and voluntary. The formation of hypothetical-deductive thinking appears when the young person has the capacity to abstract, to separate the notion of object from a concrete reality and the possibility to analyze his own thoughts. He/she begins to understand and deduce the cause-effect, singular-particular-general connections. The ability to apply in practice with an individual character is also formed - the young person has the tendency and ability not only to acquire new knowledge, but also to use it to create something new, integrates it much better [6].

Young people go through new challenges once they enter the university/vocational education system related to important exams, different classification system, different grading system, different type of examination, university structure and so on.

1.2. Self-training

Youth has an emphasis on the need and desire to learn more on their own, with autonomous effect. A style that focuses on the need for continuous renewal of one's knowledge through a constant personal effort is preferred, an effort that opens the perspective of developing the skills to learn alone, of autonomous and independent training. These self-taught systems will gain ground, because they respond better to self-motivations, an internal motivation for self-improvement and training, for self-completion, each individual having the opportunity to cultivate and better value their own abilities. and skills. Thus, the individual becomes his own "manager" of his intellectual, cultural and professional progress and plays an active role in the development of his cognitive function and his own training.

Self-training is defined as an integral part of self-education [7], which refers to the enrichment of knowledge and independent intellectual training. It involves a motivational impulse and the acquisition of tools of independent intellectual work. Individuals create their own self-training system, with personal, adapted techniques, which are based on his style. These involve: choosing the necessary information, systematizing it, processing the learning content, using the content to solve some learning tasks (exercises that help to integrate the learned content), self-control and so on.

Self-training is considered a form of manifestation of cognitive activism [8], a difficult and complex process that is not summarized only during university studies, but throughout the life of the individual. It is considered that the self-taught activity requires great efforts, ability to organize, to organize his/her own personal space, concentration on the task, developed motivational sphere, permanent control and self-improvement. This type of learning is common in high school. It is based on awareness and formation of personal appreciation of the domain taught. Metacognition is the theoretical foundation behind self-training. Self-regulated learning is based on self-responsibility.

The following question also arises: why a person cannot have a self-regulated learning throughout all learning experiences. Other theorists [9] believe that, when they are young, children cannot be self-regulators during learning in any formal way. In addition, comes Piaget's theory [10] that explains that against self-learning learning comes the egocentrism of the young child. And Vygotsky [11] emphasizes the importance of young children's inability to use inner language in guiding roles.

It is important to mention that the self-training activity must in turn be learned and repeated. Students go through many attempts in order to find out what is their personal style of deepening the teaching courses, their contents. Dordea [12] states that there are three sub-competencies that students must master in order to succeed in the process of self-teaching: self-appreciation of the personalized strategy, realization/implementation of that strategy, self-evaluation of results. Basically, the student has to "learn how to learn".

The individual learning project can be improved through two main ways: 1) indirectly, through experience; and 2) directly, through training. Thus, individual study can be encouraged through recurrent positive experiences (students notice that self-assessment is positive and that self-instruction increases the accuracy of learning), similar to the theory of positive reinforcement.

It is important that adolescents and young people acquire self-regulatory skills during their development. As the time passes, they need to process an ever-expanding volume of information and operate with knowledge at increasingly abstract levels. An essential feature of self-regulated learning is the dynamic approach of the topics to be learned. Thus, the student can analyze the teacher's comments and compare them with his own perceptions of the learning situation. Can self-learning lead to a burn-out syndrome due to the pressure and informational volume? Recent scientific research based on evidence-based medicine is highlighting the increased number of young people that are developing burn-out syndrome, sometimes due to medical conditions (neuroendocrine for example) that leads, in the severe form, up to depression [13].

The situation of students who become pregnant at a young age should also be discussed as a separate perspective (even if they have a lower frequency in the University of Medicine or Sports, given the specifics of learning or activities/ practical works). However, their number should not be neglected, especially in terms of pregnancy hormones, which cause mood swings, which can influence the ability of learning, given the motivational-volitional links with those of mnesic-prosexic processes and learning, especially in the amygdala area and the hippocampus area, brain areas significantly involved in both emotional motivational regulation and superior gnostic functions, so that they are active at the optimal level in terms of supporting the effort to complete a university curriculum [14, 15].

1.3. Adult education

The educational process of adults must respond to the challenges posed by today's society, which is changing its rhythm very quickly. Giddens [16] proposes a series of characteristics of late modernity, as typical elements for contemporary western society: industrial capitalism, reflexivity, individual responsibility. Modernization has accentuated digital education, with the help of digital technologies in many fields, from trade to education, medicine, teachers [17].

Adult education in Romania takes place in the context of another type of modernity than that of the western countries, namely tendentious modernity [18]. This concept refers to the fact that there are differences between the style in our country and the western one, due to some older concepts in our system, which makes the modernization to be partial and unfinished.

Adult education occurs only by virtue of personal own vision of the project of developing society, with all the implications of the coexistence of the old with the new, of progress with conservatism, of the modern with the traditional. It aims to improve existing skills and/or acquire new ones. It also aims to assimilate system values that have previously proven social performance and put them into practice. Adult education asserts itself in different forms of education: continuing education, non-school education, non-formal education.

There are a number of phenomena that prevent the formation of adults: inequality of opportunities in education, inequalities between levels of education (between educational units from the same area, between students), inequalities of access between faculties. In several cases these inequalities have a huge impact on the developing personality of an adult person even more if this personality closes the borderline type or reaches the psychiatric connotations [19]. There are several causes that are against unitary access to educational levels: poor material endowments, underfunding of educational units, differences between schools in urban and rural areas, problems related to human resources in schools, school dropout, repetition, the existence of a segment of the population that does not take advantage of the educational system. The higher the level of schooling, the higher the value of the additional costs of education that the family has to cover, discussing here for example: the fee for college, food expenses, textbooks, rent [20]. Nowadays, recent strategies involving the cost of education are trying to keep the step with full on-line education system, additional costs covered by the family have changed their levels: for example, a higher investment in modern communication devices. In the same time, the educational system redirects its costs based on this new on-line strategy.

Lifelong learning involves everything a person does throughout life to complete his/her knowledge, learn new things, acquire skills or develop his/her talents in formal, non-formal and informal contexts.

It is important to note that education, from one level onwards, is optional. Post-school training is often a personal choice. Unfortunately, there are no mechanisms in society to encourage adults to learn continuously. They may limit themselves to the knowledge gained in school due to routine, inability to cope with change, difficulty in economic and financial management, disinterest in performance.

It is observed that young people who have obtained a higher education have: information processing capacity that can be extended to other cognitive areas, the operability of thinking is kept at high levels, the young person's thinking is wide, deep, systematic, rigorous, very good mental adaptability to specific professional. Young people have critical thinking [21].

1.4. Evaluation - types of evaluation

Evaluation is a component part of the educational process. It informs us about the effectiveness of teaching-learning strategies and methods and appreciates the correct choice of operational objectives on lessons. The teaching-learning-evaluation relationship presupposes a cause-effect circle, in which each component conditions the other. If we are thinking at the western model, the evaluation should not be considered a control method that would punish those who fail it. Students must understand the learning content, not only memorize it, and the given task must be contextualized, in which the subject can express his/her learning style.

Evaluation can be of several types. It differs depending on the type of classification. According to the criterion of the moment at which it is performed, the evaluation can be:

- initial (in the initial phase of the instructive-educational process) - aims to see what is the level from which to start,
- continue (throughout the training program) - aims to observe the improvements along the way and to achieve the optimization of the educational process,
- summative (at the end of a session/module).

The evaluation can also be: formal and informal. The formal one presupposes well-defined criteria, previously outlined and it is associated with standardized tests, it presupposes a certain level of expertise of the one who performs it (License type exams, Baccalaureate, National Assessment etc.). Informal assessment is based on intuitive criteria and involves tests created by the teacher.

There is another classification of evaluation: internal or external. The internal one is made by the internal teacher (the one who designed the learning content is the one who evaluates it). In this case, the evaluator knows the particularities of the students, is familiar with them, knows their progress along the way. The external evaluation is performed by a teacher who has not been involved in the instructional-educational process and has the advantage that it is objective.

The evaluation can also be of normative and criterion type. The normative one has the following characteristics: the performance of the subjects is related to the group norm, to the reference group (class, year, respective series) and compares the students, it ranks them. Criterion evaluation presupposes that performance is related to an absolute criterion, to a standard. Evaluate absolute success in evaluation.

According to some other authors [22-24], evaluation can be: comparative (has the role of classifying subjects, relating them to each other, according to their level of success), based on a criteria (has the role of providing functional information, allowing subjects to be in in relation to achieving the objectives common to all subjects), corrective (wants to provide the subject with additional information depending on the difficulties he encountered), conscious or formative (oscillates between cognition and metacognition and promotes active participation and autonomy of the subject so that he/she, subsequently, takes control of his/her own transformation, becoming aware of its shortcomings and difficulties).

The traditional assessment methods are: oral tests, written tests and practical tests. There are also complementary, more modern methods, among which: systematic observation of behavior, investigation, project, portfolio, self-assessment [25].

Sometimes the psychological and physical overload based on a frail personality structure could lead to an interpretative phenomenon of key components of an evaluation, that, for the student, seems to be debatable. Risks will lead later on to anxiety and depression sometime at psychiatric levels [26, 27].

1.5. Summative evaluation

It is also called cumulative evaluation. The act of evaluation involves three stages: measurement, assessment of results and adoption of improvement measures [28]. It is performed at the end of a session/module. It has the purpose of accreditation/decision to improve future activities. It is performed by an internal or external evaluator, is done at long intervals and aims to see the final results of the students. It tries to test the final and accumulated knowledge that the students have acquired. It is important because of its dual role. It is useful for the trainer, to see if the chosen means and methods are useful, effective, if the information has arrived correctly and as quantitatively as possible. It is the feedback he receives from students. It is also useful for students to objectify what information they understood, what should have been clarified in more detail, etc.

It is a type of balance sheet assessment, global, at the end of relatively large activity segments. The disadvantage of this type of evaluation is that it does not allow the regulation/ improvement of the didactic process; it is possible only after relatively long periods or never. Thus, trainers cannot change the teaching-training style to improve the results of their students, because they cannot make a second summative evaluation. However, it highlights the level at which the activity took place and its results, recognizes the efforts made by the subjects and the interest shown by them. It also offers the satisfaction of the social recognition of the subjects' competencies. At the level of society, these cumulative assessments certify that subjects are able to cope with certain tasks and requirements and that they can play certain roles in social life.

It is well known that grades, often, do not exactly reflect the true level of performance of the subjects and as a result, are not stimulating and do not provide sufficient data on the effectiveness of the training program. It is advisable to use it together with other types of assessment, such as continuous assessment, to rely on continuous feedback to cooperate the teacher with the students [29].

MATERIALS AND METHODS

The present research aimed to highlight some differences in the learning-teaching process of young people at the level of students at the Faculty of General Medicine, compared to those at the National University of Physical Education and Sports. We tried to observe what is the time that young people aged 18-25 allocate for individual study in their preparation for the summative assessment and the level of awareness of the need to be involved in the self-taught process. We highlighted the perception of students in relation to the teaching style of academics. We also sought to highlight possible psychological motivational explanations for interpreting the results.

The tool used was a questionnaire that consists of 21 questions (11 questions are related to the individual study process of young people in the group, and 10 are about the teaching process sustained by the professors at courses), along with four more questions to highlight the factual data. It is an opinion questionnaire. The participants received the appropriate training to complete the answers and were assured of the confidentiality of the data, their results being used only for the purpose of this research. The questionnaire took about two minutes to complete.

The tool was uploaded in google forms and sent to the participants to form the database. The data were collected between April 15-25, 2020.

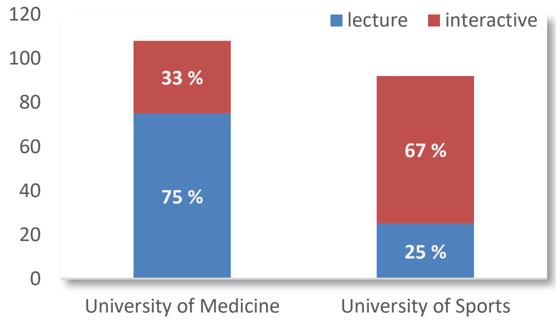
The study was performed on a number of 31 participants. The group was divided into two groups: 16 students in the 5th year at the University of Medicine and Pharmacy- Faculty of General Medicine and 15 master students in the second year at The National University of Physical Education and Sports, the Motor Performance program.

The ages of the participants ranged from 22 to 26 years. There was female (18) and male (13) participants.

RESULTS

Regarding the methods of education and training in young people, we highlighted the teaching style of the university staff from the two faculties and we noticed differences between the style of them, one activating in the field of health and the other one in the field of sports (Figure 1).

Figure 1: Teaching style of academics (percentage of teachers)

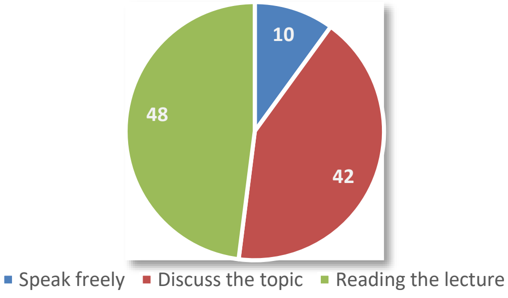


Although, currently, the teachers from the medical university are increasingly open to a more interactive teaching style, it is important that a well-structured lecture is based on a diagnostic tree, and the mastery of logical thinking by the medical student implies, in for the most part, the acquisition of diagnostic tree-type thinking. This is the reason why many medical teachers prefer a lecture style because it is better suited to the large learning content, compared to those in the field of sports that emphasize the practical part of the theorized content.

Medical professors focus more on teaching "thick materials" in a lecture-style method when they are addressing to a homogeneous group of young people, with preliminary and extensive concepts from the pre-clinical years and for whom the information presented makes sense and it is easy to understand. For more difficult subjects, students prefer a direct teaching method, in which they manage to write down the information as accurately as possible, in order to have the chance of a second or third passage through the materials represented by their own notes, in the idea that the information it was so abundant that the student (less familiar with information gaps from previous years) could not be assimilated. For such students, who have become more accustomed to the learning required to go to the University of Medicine, the lecture-method makes it less difficult for students to be less thorough, as they need accurate exposure of information and at a slower pace, so that the lesson can be more easily assimilated.

Regarding the presentation style of the information in the courses, the total distribution at the level of both faculties is presented in Figure 2 – presentation style. We consider that it is a too high percentage of teachers who read the presentations in the courses, being more a monologue type course, than a bidirectional one in which the information is incorporated by the student. It is true that of this 48%, 66% of respondents were medical students. This suggests, again, that the need for knowledge, the dictionary that future doctors must master, is much greater than that of sports specialists. Thus, it is absolutely necessary for health teachers to exhaustively expose, perhaps sometimes arid and dull, medical terms that students must master.

Figure 2: Presentation style

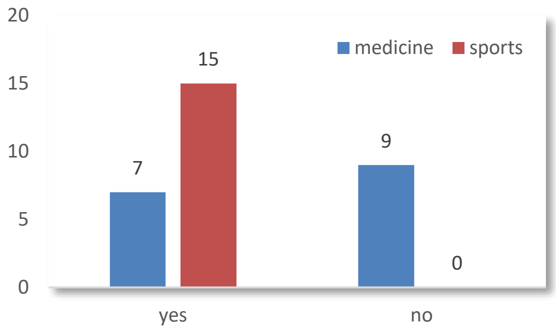


This research can show the need for certain teaching materials that must be presented in a readable and slow tempo. This need is related to a psychological concept regarding the teacher's ability to establish a connection between the unconscious mind of the students (who gradually enter in a learning state) and the unconscious mind of the teacher (the later having a more systematized information). The slow tempo prepares the student to enter the scientific atmosphere in a preliminary psychic state, kind of an awaiting state of mind for the "key" information, which comes gradually. The student must receive the information with the same curiosity, interest and respect for the simple information. These will represent clues for the future job, because the causal links cannot be understood exactly if the students expect only interesting and spectacular information and they pay attention only when these are exposed.

Most students (81%) of both groups estimated that a course has about 10-20 pages. All subjects accepted that they reopened the materials for the information taught in their practice.

To the question that probed the need to individually read and understand the content of the courses, the students from the sports university answered, in a percentage of 100%, yes. On the other hand, in the group of medicine students, the distribution was uneven. This shows us that at the university of medicine is a much more detailed and exhaustive content that requires explanations from teachers, while at the sports university is more emphasis on the practical side, students having the necessary knowledge to understand the content of the courses. The explanation can be seen in the Figure 3.

Figure 3: The need to extract the main information individually from the course content (number of students)

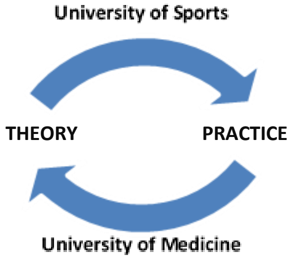


Regarding the information presented at either of the two faculties, if we refer to the high-level learning, more exactly, the preparation for master's or doctorate for UNEFS students versus the preparation for bachelor's or residency for medical students, it is necessary to explain the detailed information in time, for longer periods in terms of dosing effort. It is well known that for grade 7, students must go through the subject once, for grade 9, twice, and for grade 10, three times. This is especially important for difficult materials, which include arid parts (and less practical demonstrations), the preclinical subjects in the first years of the Faculty of Medicine or the theoretical parts of some less publicized sports. Also, the preparation of any important exam involves dosing the effort, thus, in the first days one learns about four-five hours a day, and in the last ten to fourteen days, in the memory has to run for the last time the whole subject, with the intelligence to focus on the key concepts and logical causal links.

The results showed that most medical students' courses have more than 7 pages, which makes them spend more time learning the content needed for summative assessment. It should be noted that the material to be learned from the Faculty of General Medicine follows a general pattern that involves a predetermined order: prevalence and incidence of the phenomenon/disease, etiological aspects, pathophysiological aspects, characteristic symptoms, their grouping in syndromes, main diagnosis, differential diagnoses, evolution and prognosis (positive factors, negative factors), treatment options. It is known that most of the time is spent understanding the pathophysiological mechanisms behind the diseases, but in the field of health it is absolutely necessary to go through these arid mini-chapters to understand the phenomenon in full, compared to specialists in sports, where the accent is on practical application. In addition to changing/developing learning skills in relation to the age and experience in student years, learning styles also change in relation to the years spent in a particular faculty, with the involvement in adapting to the specifics of that faculty. This capacity of adapting involves flexibility of thought and intellect and, of course, experience. Once familiarized with the most important concepts in the field of activity, after about five years in a faculty, students, master students, doctoral students or residents achieve the performance of reading about 20-30 pages of scientific content with which they are familiar, without feeling the effort, with pleasure, interest and the possibility of thinking in parallel for developing their own opinions. In the last category, the teaching-learning mechanism is reversed, starting from practice to conceptualization, which is more attractive for students because they enjoy the results of concrete work faster (Figure 4 – the learning processes).

At the level of both educational structures, students similarly reported the need to take notes during the courses, but two respondents from the medicine university noted that most courses receive written support which made them not need to take notes. We emphasize here the importance of distributing written course support to students.

Figure 4: The learning processes.



We consider that the educational instructional process is much more effective in the case of the existence of written materials after which the student can be guided later, during the individual study process. The main activity of the student during the course should be to focus attention on the topic of the course, on the information that the teacher has to offer. We are trying to adhere to a western education system, in which the modernization of the process with the help of technologies is desirable. We consider it appropriate to emphasize the link between taking notes and the facilitation of the active memorization, later learning and reproduction the material. There are students who manage to go through large materials (hundreds or thousands of pages) through active learning and using a specified type memory, the one from which the information drains unconsciously in a passive way. Others are focused on compiling their own notes, on taking notes, failing to store information if it is not processed and systematized in their personal way. We do not comment on the superiority of any of these techniques, but we want to emphasize different ways of how the mind function. The personal notes, as the individual dedicates himself to the profession, can become more and more schematic, becoming understandable only by the one who writes them. These personal notes can exclusively define causalities, "key" concepts, inferences, connections and fewer mnemonic formulas (these being typical for an earlier stage learning).

Another aspect to note is the desire for the lecture not to be completely similar to the course support and it proved to be more efficient to listen to the lecture, when the student does not focus on finding those notions in the written material, but on understanding the explanations given by the teacher and following the logical thread of the lecture, proving much more effective than the situation in which the student reads the learning content beforehand. The notions described in medical courses are difficult, imply new and unknown terms to the student, which makes it important to lecture and especially to be accompanied by explanations, examples that make the learning content more accessible. That said, the lecture is a material more understandable to the student than some course notes in medical terminology. In this case, the role of the lecture is to lower the level of understanding from abstract to concrete, from general to particular. Instead, in the sports environment, the provision of specialized materials is more easily accessible at first reading even to an audience unfamiliar with the field, but the difficulty lies in the practical applicability of the theoretical content.

In both Universities, students rated similarly on a Likert scale from 1 to 10 the "weight" – the difficulty of a course, somewhere at a grade of 7-8. This suggests that the teaching content is reported to the type of students taking part in the course. Thus, the participants do not have a comparison model, all the courses are of the same similar level within his university. At the both faculties we suggest the need to introduce courses with graded difficulty, thus the difficult subject is exposed at the, approximately, seventh-eighth meeting with students, after they have acquired interest in the studied information and have sufficient knowledge to be interested in deepening the subject.

We wanted to probe the students' conscientiousness about the self-instruction process for summative assessment. The Figure 5 shows the difference between continuous learning (throughout the year) and discontinuous learning (exhaustive period during the session, in which they only prepare for assessments). For medical students, there was a longer distribution of the self-taught learning process, instead, the sport university students organize their learning time in the last part of the semester.

Figure 5: Distribution of the self-training process over a longer period of time (number of students)

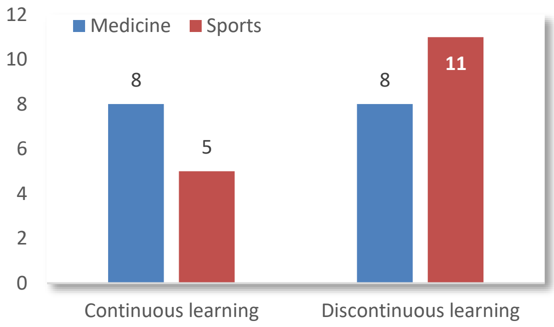


Figure 5 shows that the distribution of medical students' conscientiousness is divided equally between those who study continuously and discontinuously, while in the category of students at sports university, most of them learn the theory for the exam shortly before it.

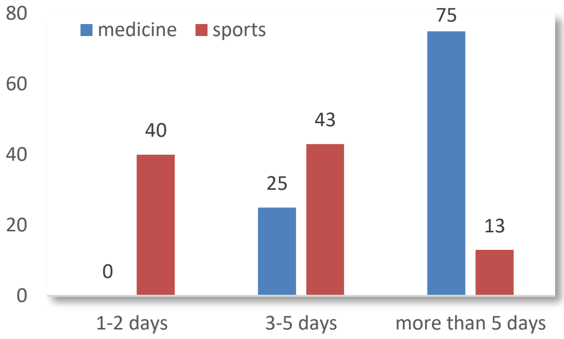
Among the explanations, we thought about the aspect that, in both situations, the practice of that profession has two components: the practical part (working with patients versus working with students) and the conceptualization part which involves talking and theorizing what you do. For the doctor, we refer to the composition of the observation sheet, the possibility to explain the case and the scientific research; and for sport coaches and teachers, it involves the lesson plan, the training plan, the monitoring through observational feedback. Medical students, from year 3, go to hospitals, see clinical cases that arouse their interest, receive partial or incomplete explanations from their seminarians about solving the case. Thus, the interest to learn more is aroused, and with the help of modern forms of learning (internet, for example), their curiosity makes them look for information and learn more constantly through the challenges from practice to theory. This learning is not necessarily a systematized one, but it puts the student in a greater contact with the learning content.

The students at the sport University are concerned with everything related to the development and refinement of personal practical skills, but also of the subjects they work with, their goal being to accumulate their own experience as rich as possible from working with as many individuals and less to take from the experience of other colleagues, because the coach-athlete/teacher-student relationship is more personalized and longer lasting than the doctor-patient one (especially in the emergency medical branches and not in chronic diseases). However, there are also some long-term doctor-patient relationships, such as these in chronic diseases (such as psychosomatic, rheumatological, oncological diseases, which require time dosing the treatment regimens and proper management, both somatic and psychological). Such relationships are of the adult to adult type (when the patient is responsible for dose adjustment depending on the acute symptoms present), parent to child relationships (which are sometimes necessary when the patient himself is a doctor and such an attitude becomes useful for making the patient in question listen), friendship-type relationships (where the doctor goes from being an “enemy of the disease” to being a friend of the patient, a counselor, a trusted person who helps the patient not feeling the limitations imposed by disease). Similarly, the athlete-coach relationship can: define the coach’s domination (in terms of his personality and executive function) or transform the coach into an advisor of training, shifting the responsibility to the athlete. In the later type of relationship, the coach becomes guide for optimal and efficient development of his athlete. The coach can be a mentor, a friend, an advisor, an authoritarian superego, who controls the desires and objectives of his athlete and the dosage of efforts, but always maintains the high-performance standard.

We objectified that most medical students give for the learning process over 5 days before an exam, while those at the sports University give 1-5 days. The uneven distribution can be seen in the Figure 6.

Figure 6: Distribution of days granted for learning process, compared between the two universities (percentage of the students)

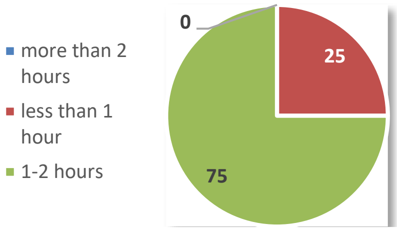


An explanation of the phenomenon could be that those medical students who give more than 5 days are those who, over time, have formed a structured thinking, to learn in steps, from micro aspects, to macroscopic aspects, from pathophysiology and etiology towards the logical understanding of the formation of the symptoms characteristic of the respective disease. In another category are those medical students who believe that diseases should be acquired from the clinic to understand the etiology and thus, they intentionally omit the arid part of the learning content, believing that it operationalizes learning. Many of these "more efficient" students can get high grades in practical exams, maybe even at oral ones, where the teacher requires only the clinical conceptualization of the case, but still a deeper approach will reveal the gaps in understanding the etiopathogenic phenomenon

We sought to probe the maximum time a young person can stay focused in a learning activity in late adolescence and whether there are differences between the training and the profession they choose, differences that will influence their ability to concentrate. From the collected data, we did not discover significant differences, which leads us to think that this capacity depends on certain internal factors and on the stage of personal development. This can be seen in the Figure 7.

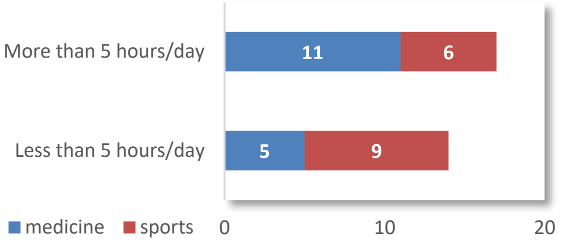
The psychological explanation of this phenomenon can be in the concept of endurance and the development of long-term endurance in terms of staying longer and longer in contact with notions, concerns, problems, conceptualizations of the chosen profession. The faculty and the acquisition of information during it are only the preamble, endurance itself is obtained with the practice of the profession, important roles having curiosity, self-improvement, desire to be up to date with news, desire to interact and exchange information with other professionals. We consider that the age range of 18-25 years is the one in which the foundations of endurance are barely laid and still different students are looking for the right techniques for acquiring information, sweeping between what would be easy from theory to practice or to practice in theory ("learning to learn").

Figure 7: Concentration endurance



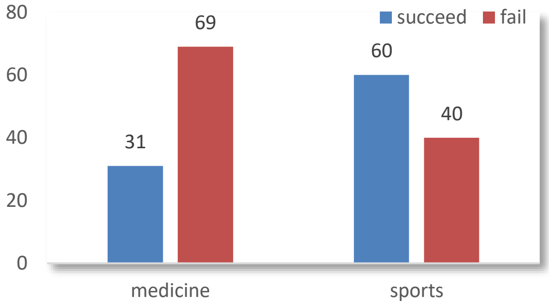
We found that there are significant differences between group samples in terms of the maximum number of hours per day spent for individual study. The percentage of those who spend more than 5 hours a day for individual study is in medical students' area. This demonstrates that they make greater efforts to self-train, have a greater ability to organize, focus on the task, a higher motivational motive, but also the desire for self-improvement more developed than in the field of physical education. The distribution can be seen in the Figure 8.

Figure 8: The maximum number of hours per day spent for self-training (percentage of the students)



We also probed the importance of the self-taught process, by asking the need to study at home the material presented in the course to pass the final exam. We wanted to emphasize that medical students need a period of self-improvement, a period of in-depth assimilation of the information presented to the course or practical work, compared to those from a sports University, who managed to pass the exams based only on the knowledge assimilated to the courses (Figure 9).

Figure 9: The process of passing the exams based only on the knowledge assimilated to the course (percentage of students)



DISCUSSION

There is a major difference between the style of teaching knowledge for students in the two faculties - the mechanism for medical students is from theory to practice; while for students in the field of physical education, the learning mechanism is reversed, from practice to the formulation of theories.

The field of medicine has been developed for thousands of years, and during all this time, specialists have learned to work simultaneously: in one plan to diagnose and treat, and in the other to make explicit, theorize, generalize, argue, and develops an inferential and dichotomous thinking. They have developed their own style of communication between specialists to convey key information in operationalized and synthetic concepts. Thus, 66% of medical students perceive that the teaching style of teachers regarding the medical dictionary must be mastered as being much focused on the presentation of information and less on practical applicability. Instead, sports coaches or teachers have recently started to focus on the conceptualization of their work, on quantification, on operationalization, on ways of exchanging information (to external sources such as: psychologist, athlete's family, school leader, etc. or between them as specialists).

100% of the students from the sports University consider that they need to inspect the learning material themselves, but it is very important that they have the necessary information to understand it individually. In the field of coaches and sport teachers, the emphasis was on the practical side, on streamlining the educational-instructional process, on refining personal skills, on developing the means and methods of teaching the learning content.

Teachers in both faculties should focus on lecture-type teaching, but not identical to the written material; they have to include examples, follow a red thread (message to take home) and ensure that it has been passed on to the student.

Along these lines, students should be considered active partners in the teaching process even if their level of instruction is much lower than the teacher’s one and even if there are significant differences between participating students in terms of previous level of knowledge, involvement, curiosity and motivation. The teacher's role is to modulate the "global intelligence of the audience", encouraging the obviously participatory students and stimulating the less interested ones. It would be a didactic mistake to have the preconception that the overall intelligence of the audience is low, which may lead the teacher to lower the level of the lecture or consider that it is no longer necessary to provide complete information, omitting examples and features or not presenting parts considered more difficult. Students similarly rate the weight of the courses on grades 7-8, which demonstrates that the learning material is hard enough to keep them focused and grasp in their understanding, but easy enough not to lose them and to be at their level of knowledge.

Among the teacher's tasks should be to increase the student's endurance (making him forget how time passes), involving him in active listening in which the student's thinking becomes a partner of the teacher's thinking in understanding the chain of information explained (even if it not perceived). We notice that in young people aged 18-25, endurance is limited to 1-2 hours mostly, but it is acquired by stimulating logical thinking, memorization through vivid representations with reference to clinical cases and practical applications. It is also known that during this period, students are still learning how to improve themselves, how to learn information more effectively, learn how to learn. At the end of the lecture, the student must remain in a still active state, with the desire and curiosity to look for a minimum of personally discovered information regarding the topic of the course presented. Also, the student's thinking must remain during the lecture able to compare the newly received information with a previous knowledge database, which helps him to make his entire previous notional system richer and supported on a more solid basis.

According to the scientific literature, the period of late adolescence is considered a maximum in terms of the ability to assimilate new information, as well as curiosity and openness to it, the desire to filter and systematize it according to personal experience. Therefore, the teacher must teach them a material appealing to the maximum capacity that he intuits as being present in these young people, crediting them with motivation, life choices, determination for the profession, the belief that they will never give up self-improvement.

ORIGINAL ARTICLE

Comparison of complications of surgical repair in inguinal hernia with Bassini, Lichtenstein, and preperitoneal methods

Seyed M. Khatami[1], Shaban Mehrvarz[1], Jamal Akhavan-Moghadam[1], Hadi Khoshmohabat[1], Hamed Gholizadeh[1], Yasser Hosseinzade[2], Mohammad J. Babaei[1,3]

Abstract: *Introduction: Complication after inguinal hernia repair is one of the challenging problems after inguinal hernia repair. This study aimed to compare the complications of three common surgical methods in inguinal hernia repair, Bassini, Lichtenstein, and Preperitoneal methods (with anterior approach).*

Methods: In this prospective study, patients who underwent inguinal hernia repair surgery in Baqiyatallah Hospital from June 2019 to May 2020 were included. Patients were allocated in three groups: Bassini, Lichtenstein, and Preperitoneal (with anterior approach), based on surgeons' opinions. Postoperative pain, hematoma and seroma, wound infection, recurrence, and also we assed postoperative satisfaction after surgery.

Results: The mean age of patients was 49.90 ± 16.44 years, and 92.5% of patients were male. Of the total patients, 6.8% had an infection and there was no significant difference in the distribution of infection in the groups (P=0.230). The mean of pain in all patients was 2.37 ± 1.10. There was no significant difference between the three groups in the mean of pain (P = 0.253). There was no significant difference in the distribution of recurrence in the groups (P=0.356). There was no significant difference in the distribution of testicular swelling in the groups (P=0.421). No postoperative hematoma and seroma were reported in the groups. The mean of satisfaction in all patients was 93.61±19.63. There was no significant difference between the three groups in the mean of satisfaction (P = 0.156).

Conclusion: The results showed that infection, pain, and recurrence rate in the Preperitoneal group were lower than the other groups, although this difference was not significant. Also, testicular swelling, hematoma, and seroma as well as patients' satisfaction were similar between groups.

Keywords: *inguinal hernia repair, Bassini, Liechtenstein, preperitoneal*

INTRODUCTION

Operation of inguinal hernia is one of the most common procedures in the general surgery field. The prevalence of inguinal hernia is between 15-45% in different ages [1-3]. There are two categories for inguinal hernia, direct and indirect, that included 24 to 50% of all types of hernia, respectively [4-7]. Some studies reported chronic obstructive pulmonary disease, chronic cough, benign prostatic hyperplasia, chronic constipation, family history of hernia, previous right lower quadrant incision, smoking, collagen diseases, physical activity, and bearing the burden can trigger inguinal hernias [5-10].

The inguinal hernias can develop discomfort, pain, and dysfunction in the patient, and also it can cause a cosmetic problem for most patients [2-4]. Severe complications of this disorder, which often occur following hernia entrapment and suppression, require emergency intervention. These include obstruction, ischemia, and gangrene of the bowel or any organ trapped inside the hernia sac [4-7].

Surgical procedure is the standard treatment of this disease. Today, there are several techniques of surgery for it, and surgeons associated with circumstances chose a surgery

strategy. The main purpose of surgery is to treat patients and decrease the recurrence chance of the disorder [11-15].

Inguinal hernia repair surgery has several potential complications such as hernia recurrence, pain, osteitis of the pubis, Damage to the cord and testicles, hematoma, and testicular swelling [1-3, 5]. There are two main approaches to operation including open surgery and laparoscopy. Also, there are several techniques to repair the herniation site such as classical and preperitoneal techniques. The classical method is a simpler procedure than other methods of repair conducted by most surgeons. Various conventional methods like Bassini's applying suture material are in usage despite the laparoscopic hernia repair [16-18]. Suture repair is related to a significant tension on the suture line. This is possible to induce ischemia of the tissues and final failure of repair causing recurrence [18-20].

Open surgical techniques include two categories of tissue repair and mesh repair methods. More traditional methods are based on initial tissue repair, but today with the production and presentation of industrial meshes, non-traction hernia repair with mesh is the standard method of inguinal hernias surgery [9-6]. Lichtenstein et al. reported the concept of tension-free hernia repair through a synthetic proline mesh that ensuring promising outcomes of hernia repair in the long term [1-3].

Preperitoneal repair is one of the pre-peritoneal methods, the mesh is placed under the transversal fascia and right on the peritoneum, and especially in cases of recurrent hernias after tissue repair methods. In this method, the peritoneal space is released through the anterior access, a 15 by 15 cm mesh is implanted on the peritoneum and fixed to the umbilicus and symphysis of pubis with non-absorbable thread, and then tissue repair with nylon loop thread is done [13-14].

This study aimed to compare the complications of Surgical Repair in inguinal hernia with Bassini, Lichtenstein, and Preperitoneal methods.

METHOD

In this prospective study, patients who underwent inguinal hernia repair surgery in Baqiyatallah Hospital from June 2019 to May 2020 were included.

Patients were allocated to Bassini, Lichtenstein, and Preperitoneal methods (with anterior approach) based on surgeons' opinions. Postoperative pain, hematoma, seroma, infection, recurrence, and postoperative satisfaction were assessed after surgery.

Sufficient information was given to patients about the type of different surgical techniques.

All cases were assessed and followed up according to the standard protocol. All the patients were followed up for 18 months postoperatively to assess complications. Excisional sac hernias were sent to a pathologist to examine their tissue for any malignancies. All cases were normal.

All operations were performed by surgeons in this research with a similar technique. The pain was measured according to the visual analog scale (VAS) post-operative. VAS was described for patients as a ruler that is calculated from 0 to 10. A score of zero shows painlessness and a score of 10 shows unbearable pain possible by the patients.

The protocol of the study was confirmed by the ethics committee of Baqiyatallah University of Medical Sciences with the IR.BMSU.BAQ.REC.1399.026 code. Consent forms were received from all participants.

Mean, standard deviation, frequency, and percent were reported to describe the data. Chi-square and Fisher's exact tests were used to determine the differences between qualitative variables. Data were analyzed by SPSS-20 software. The statistical significance level of all tests was considered less than 0.05.

RESULTS

Overall, 56 patients in the Bassini group, 50 patients in the Liechtenstein group, and 40 patients in the Reed-Reeves group were included.

The mean age of patients was 49.90 ± 16.44 years, and 92.5% of patients were male. The mean BMI of all patients was 25.52±3.56. The mean duration of surgery in all patients was 28.49 ± 75.97 minutes.

There was no significant difference between the groups in the sex distribution of patients (P=0.117). The mean age in the Bassini group was 18.59 ± 45.28 years and was significantly lower than the other groups (P = 0.003). The mean BMI in the Liechtenstein group was 26.95±4.13 and was significantly higher than the other groups (P = 0.002) (Table 1).

The mean duration of surgery in all patients was 28.49±75.97 minutes and there was no significant difference between the three groups in the mean duration of surgery (P = 0.226).

The mean length of hospital stay in all patients was 0.89. 1.02 days and in the Reed-Reeves group was 0.80 ± 0.50 days which was significantly less than the Bassini group (P=0.003).

There was no significant difference in the distribution of history of diabetes, COPD, and smoking between the three groups (P> 0.05) (Table 2).

Table 1: Patients' characteristics according to three groups of the study

Items	Bassini	Liechtenstein	Reed-Reeves	P-value
Age	45.28 ± 18.59	55.66±11.76	50.43±15.45	0.003
BMI	24.90±3.17	26.95±4.13	24.56±2.65	0.002
Sex	7 (12.1%)	1 (2.0%)	3 (7.5%)	0.002
	49 (87.9%)	48 (98.0%)	37 (92.5%)	

Table 2: Duration of surgery, length of hospital stay, diabetes, smoking, COPD and constipation in patients

Items		Bassini	Liechtenstein	Reed-Reeves	P-value
Duration of surgery		75.44±33.75	85.27±17.69	70.00±22.79	0.226
Duration of hospitalization		1.27±0.93	0.93±0.71	0.57±0.80	0.003
Diabetes	Yes	5 (9.1%)	4 (8.0%)	3 (7.5%)	0.002
	No	51 (90.9%)	46 (92.0%)	37 (92.5%)	
Smoking	Yes	11 (19.7%)	10 (20.0%)	7 (15.6%)	0.360
	No	45 (80.3%)	38 (76.0%)	31 (78.1%)	
	History	0 (0.0%)	2 (4.0%)	2 (6.2%)	
COPD	Yes	2 (3.1%)	6 (12.0%)	0 (0.0%)	0.050
	No	54 (96.9%)	44 (88.0%)	40 (100.0%)	
Constipation	Yes	1 (1.6%)	6 (12.0%)	8 (18.8%)	0.008
	No	55 (98.4%)	44 (88.0%)	32 (81.2%)	

The frequency of constipation in Reed-Reeves and Liechtenstein groups was significantly higher than Bassini group (P = 0.008).

Of the total patients, there was 6.8% postoperative wound infection and there was no significant difference in the distribution of postoperative infection in the three groups (P=0.230) (Table 3). No postoperative hematoma and seroma was reported in the groups (P=0.999). The mean of pain in all patients was 2.37 ± 1.10. There was no significant difference between the three groups in the mean of pain (P = 0.253).

Table 3: Infection, hematoma, postoperative pain, recurrence, and patients satisfaction

Items		Bassini	Liechtenstein	Reed-Reeves	P-value
Pain (VAS)		1.42±2.81	1.00±2.21	0.59±1.41	0.252
Satisfaction		96.96±11.22	91.42±26.45	89.65±20.61	0.156
Wound infection	Yes	5 (9.1%)	4 (8.0%)	0 (0.0%)	0.230
	No	51 (90.9%)	46 (92.0%)	40 (100.0%)	
Hematoma and seroma	Yes	0 (0.0%)	0 (0.0%)	0 (0.0%)	0.999
	No	56 (90.9%)	50 (100%)	40 (100.0%)	
Testicular swelling	Yes	3 (6.1%)	2 (4.0%)	0 (0.0%)	0.421
	No	53 (93.9%)	48 (96.0%)	40 (100.0%)	
Recurrence	Yes	7 (12.1%)	5 (10.0%)	2 (5.0%)	0.356
	No	49 (87.9%)	45 (90.0%)	38 (95.0%)	

There was no significant difference in the distribution of recurrence in the groups (P=0.356). There was no significant difference in the distribution of testicular swelling in the groups (P=0.421). The mean of satisfaction in all patients was 93.61. 19.63. There was no significant difference between the three groups in the mean of satisfaction (P = 0.156) (Tables 3).

DISCUSSION

This research assessed the complications of Surgical Repair in inguinal hernia with Bassini, Lichtenstein, and Preperitoneal methods. Among different surgical methods for the repair of inguinal hernia, the rate of recurrence and complications in the three methods was low. Inguinal hernia is a common disorder in the field of general surgery. The results showed that infection, pain, testicular swelling, and recurrence rate were lower in the Reed-Reeves group than the other groups, although this difference was not significant. Also, there was no significant difference between the three groups in the mean of satisfaction.

Muldoon et al. (2004) conducted a clinical trial on patients with an inguinal hernia by Liechtenstein and Reed-Reeves methods. The average recurrence in the Liechtenstein method was 4.3% and in the Reed-Reeves method less than 1%, but this rate was not statistically significant [16]. The results of this study are in agreement with the results of the present study.

Akhavan Moghadam et al. (2011) in Iran compared the results between Liechtenstein and Reed-Reeves surgery in unilateral inguinal hernia repair. Postoperative pain and return to work time were significantly shorter in the Reed-Reeves group. The duration of surgery and postoperative recurrence were similar in both groups, but the rate of postoperative infection was higher in the Liechtenstein group [17]. The results of this study in terms of recurrence rate and wound infection rate confirmed the results of the present study.

In the study by Van Nieuwenhove et al. (2007), Which was performed on patients with inguinal hernia using the preperitoneal and Liechtenstein methods, the mean operation time in the preperitoneal method was 20±9 minutes and in the Liechtenstein method was 35±4 [18]. In another study by Nienhuijs et al. (2007), Compared Liechtenstein and pre-peritoneal methods, 41 and 54 minutes were reported for the preperitoneal and Liechtenstein methods, respectively. The recurrence rate was 1.1% in the Liechtenstein group and 2.3% in the peritoneal group [19]. In the present study, the mean duration of surgery in all patients was 28.49 ± 75.97 minutes and there was no significant difference between the three groups in the mean duration of surgery.

Asgari et al. (2013) conducted a study on patients with an inguinal hernia by Liechtenstein and preperitoneal methods. They found that the preperitoneal method was a shorter and more significant incision length and operation time than the Liechtenstein technique. They concluded that The peritoneal technique can be a suitable and safe alternative to the conventional Liechtenstein method [20].

A study by Ghoseiri et al. (2014) in a study On 240 inguinal hernia patients and the reconstructive method of Liechtenstein and preperitoneal showed that preperitoneal surgery is a suitable alternative to conventional Liechtenstein [21].

Jayesh Gohe et al. (2016) on 80 patients with an inguinal hernia in India examined Bassine, Liechtenstein, peritoneal, and the Shouldice method in terms of time and recurrence after surgery. The recurrence rate was reported at around 2.5% with no difference between the methods [22].

A study conducted by Gatabi et al. (2018) compared long-term complications of the two methods of Basini and Liechtenstein on patients with an inguinal hernia. They found that the results of the two methods Basini and Liechtenstein are very similar It is similar, so both methods can be used as a safe method for patients [23].

Mohebbi et al. (2009) compared the quality of life and complications after preperitoneal anterior approach (Rives), herniorrhaphy, and Lichtenstein methods of unilateral inguinal hernia surgery. They reported that herniorrhaphy had a lower quality of life and more complications than Liechtenstein and Reeves methods [24]. In the present study, it was shown that postoperative complications and pain in Liechtenstein and Reed-Reeves methods are less than Bassini surgery.

CONCLUSION

The results showed that infection, hematoma, pain, testicular swelling, and recurrence rate in the Preperitoneal group were lower than the other groups, although this difference was not significant. Satisfaction was similar between the three groups.

Comparison of rinsing with chlorhexidine and matrica mouthwashes on the ventilator-associated pneumonia

Rasool S. Moghaddam[1], Mozhgan Rahnama[2], Abdolghani Abdollahimohammad[3], Mahin Naderifar[4]

Abstract: *Introduction: The present study aimed to compare the effect of two methods of rinsing with chlorhexidine Oral hygiene in patients undergoing endotracheal intubation is one of the most important tasks of nurses, and Matrica mouthwashes on the incidence of ventilator-induced pneumonia (VAP) in intensive care unit (ICU) patients.*

Materials and Methods: This is a clinical trial carried out on 80 patients undergoing oral endotracheal intubation. Patients were included in the study using simple sampling and randomly divided into chlorhexidine mouthwash and the matrica mouthwash groups. Data collection was carried out using a demographic information questionnaire and clinical pulmonary infection score (CPIS).

Results: The results also showed that most participants in the chamomile group (75%) did not have pneumonia, but the chlorhexidine group had pneumonia in 77.5% of cases. The Chi-square test showed a statistically significant difference between the groups in terms of the incidence and non-incidence of pneumonia (p = 0). Also, the odd ratio of developing pneumonia in the chamomile mouthwash to chlorhexidine mouthwash was 0.30%.

Conclusion: Considering the advantages of herbal compounds such as their low price and low risk, matrica can be considered a suitable alternative to chlorhexidine.

Keywords: *ventilator-associated pneumonia, mouthwash, chlorhexidine, matrica, intensive care*

INTRODUCTION

Pneumonia is the second most common nosocomial infection in ICU patients, affecting 27% of all patients. Nosocomial pneumonia develops in hospitalized patients for more than 48 hours and its incubation period is usually not more than 2 days. Among nosocomial pneumonia, VAP develops in ICU patients undergoing mechanical ventilation for more than 48 hours. Various studies reported VAP-related mortality between 0 and 50% [1].

Risk factors for VAP are divided into three categories; the first category included host-related factors such as old age, physical conditions, immobility, underlying disease, nutrition, and level of consciousness. The second category includes factors related to devices such as endotracheal tube and tracheostomy and intubation time, ventilator route, and gastric-nasal tubes. Finally, the third category includes factors related to employees such as poor hand hygiene and non-use of gloves [2].

Aspiration, intubation due to low level of consciousness or cardiorespiratory arrest, cardiopulmonary resuscitation, emergency intubation, and Glasgow Coma Scale (GCS)< 9 are important risk factors for VAP in the first 48 hours of intubation [3]. In intubated patients, lack of eating, reduced salivary flow, and spontaneous cleaning properties of the mouth and teeth lead to an increase in plaque accumulation [4] as well as the probability of inflammation [5,6].

Adherence to oral hygiene and care in ICU patients is one of the main tasks of health care providers and one of the basic

aspects of ICU nursing care [7,8]. Dental plaque is a good place for the accumulation of microorganisms. These plaques can be a good reservoir for pathogenic microorganisms in patients with poor oral hygiene (such as patients undergoing endotracheal intubation).

Fourier et al. demonstrated a significant relationship between dental plaque microorganisms and tracheal secretions. The plaque provides the opportunity for germs and other microorganisms to adhere to tooth surfaces. Bacteria in dental plaque act as pathogens when aspirated into the lower airways [9], and can cause VAP [10].

Pittet et al. believe that plaques increase during the first 7 days of intubation [11]. Therefore, oral care is considered one of the most important ways to prevent dental plaque formation and microbial contamination of the mouth [12].

There are two methods to eliminate dental plaque and its associated germs: the mechanical method (brushing) and the medical method (including antibiotics). One of the most effective methods to control plaque is to use mouthwash. Chlorhexidine is an antiseptic that is effective against a wide range of bacteria, some fungi, and some viruses [13].

Two studies have shown the effect of chlorhexidine mouthwash on reducing respiratory infections in patients after heart surgery, but it didn’t decrease the rate of VAP in other special departments of a hospital [14,15]. Although chlorhexidine has been recommended as the most effective plaque-killing agent in some studies [16], it is still not strongly recommended due to insufficient evidence for its effectiveness [17].

Various studies have investigated the effect of different chlorhexidine concentrations on the reduction of VAP, but the results have not been consistent [18]. Guideline from the Infectious Diseases Society of America also does not recommend routine use of chlorhexidine for VAP [4]. Besides, chlorhexidine has side effects that prevent its long-term use that incudes discoloration of teeth and mucous membranes, desquamation of oral mucosa, mouth irritation, stimulation of salivary gland stones (calculi), changes in taste, oral burning and dryness, peeling gums, and negative systemic effects on swallowing. Germ formation is also exacerbated by chlorhexidine due to the creation of an alkaline environment [12,19,20].

Therefore, to overcome the side effects of chemical drugs, World Health Organization (WHO) recommends research to find suitable natural substances such as herbal extracts [20]. For this reason, it is recommended to use non-chemical mouthwashes, including herbal mouthwashes [21]. Research has shown that the use of herbal mouthwashes such as chamomile has fewer side effects [22]. Chamomile extract has antibacterial, antiviral, and antifungal properties. The extract of this herb contains compounds that have strong antimicrobial properties against gram-positive and gram-negative bacteria [23].

Firoozian and Darvish Khezri (2015) showed that chamomile mouthwash not only reduces the number of oral bacteria colonies in healthy people but also affects the number of bacteria with different flora and higher resistance in patients undergoing mechanical ventilation than in healthy people [24]. VAP has been identified as a challenge for ICU personnel [25], therefore, prevention is a priority in ICUs [26].

Grap and Monro stated that oral hygiene and care as one of the most important components of nursing care should be taken into account [27]. Therefore, nurses who are in direct contact with the patient are expected to play an important role in preventing nosocomial infections, especially VAP [28]. Despite the high prevalence of VAP in ICU and the importance of mouthwash in its prevention, the prevalence of this dangerous complication has not been lower than expected despite the use of various solutions [26,29].

Also, considering the importance of using methods with minimal complications and risk that promote oral hygiene in the care of ICU patients, the widespread use of chlorhexidine mouthwash as a common solution in ICUs and due to its side effects and also the absence of these side effects in chamomile and instead its beneficial effects such as antibacterial, soothing and anti-inflammatory properties of this herb, it is recommended to use this herb if it is as effective as chlorhexidine in terms of antimicrobial performance.

It should be noted that antimicrobial effects of these mouthwashes on pathogens were investigated in vitro more frequently, and since there is a difference between ICU patients with outpatients in terms of the type of microorganisms, body resistance, and oral immunity, on the one hand, and despite the importance of preventing VAP in reducing mortality, reducing care costs, and reducing the length of stay [30], on the other hand, the present study aimed to compare the effect of two methods of rinsing with chlorhexidine and matrica (chamomile) mouthwashes on the incidence of VAP among patients admitted to ICU Department of Imam Reza Hospital in Birjand, Iran.

MATERIALS AND METHODS

This clinical trial was performed on ICU patients in Birjand in 2020 to compare the effect of rinsing with chlorhexidine and matrica mouthwashes on the incidence of VAP. The sample size was estimated at 36 people per group based on the formula $n = (Z_\alpha + Z_\beta) \times \left(\frac{(p_1+q_1)+(p_z+q_z)}{(p_1+q_1)^2}\right)$ and taking into account the result of Rakhshani et al.'s (31) study on the incidence of pneumonia before and after the intervention in chlorhexidine and matrica groups (p_1 = 0.93, p_2 = 0.80, α = 0.05, and β = 0.1). The minimum sample size per group was increased to 40 people to increase the accuracy and power of the test, considering the special conditions of patients, and the duration of the study.

Inclusion criteria included obtaining the consent of the patient's guardian to participate in the intervention, patients aged over 18 years of age and under 65 years of age, no oral and maxillofacial injury, no cancer or diabetes and chronic obstructive pulmonary disease, no immunosuppression by drugs or specific diseases, intubation in the first 24 hours and patients who are expected to remain intubated for at least 72 hours, CPIS< 6 upon admission, GCS < 9, no antibiotics before and during hospitalization, natural teeth and having no more than 6 artificial teeth, no use of anticoagulants, no history of allergies to herbal compounds. Exclusion criteria also included death or transfer of the patient from the studied ward, removal of the endotracheal tube before the end of the study, the occurrence of overt aspiration during the study period, reintubation due to the removal of the endotracheal tube for any reason during the first 5 days, sensitivity to mouthwash, the patient's guardian stated unwillingness to continue the study.

In this study, 80 anesthetized eligible ICU patients were selected by convenience sampling method and assigned to one of the two groups of chlorhexidine mouthwash (n=40), chamomile mouthwash (n = 40) in the order of time of admission using simple random sampling and a random number table. Oral care and rinsing were performed using chlorhexidine mouthwash in one group of patients and chamomile mouthwash in the other group. The frequency, duration, and manner of using mouthwash were the same in both groups. At the baseline, informed consent was obtained from the patient's guardian or legal guardian, after explaining the study process and informing him/her. Then the demographic information, medical history, cause of hospitalization, and drugs used were recorded in the information list. All patients were evaluated using CPIS and the results were recorded in the relevant form.

This instrument consists of 6 subscales including:

1. Temperature (score 0 if temperature 36.5 ≤ T ≤ 38.4, score 1 if temperature 38.5 ≤ T ≤ 38.9, score 2 if temperature T <36.5 or 39 ≤ T 2 points)

2. White blood cell (WBC) count (score 0 if 4000 ≤ WBC ≤ 11000, score 1 if WBC> 11000 or WBC <4000, score 2 if WBC> 1100 or WBC <4000)

3. Oxygenation (score 0 if 240 <or ARDS, score 2 if ≤ 240 or no ARDS)

4. Chest radiography (No infiltration (score 0), diffuse infiltration (score 1), local infiltration (score 2)

5. Tracheal secretion culture (pathogenic bacteria did not grow or there is a small amount of them (score 0), moderate to high growth of pathogenic bacteria (score 1), growth of pathogenic bacteria of the same type seen in gram staining (score 2)

6. Volume and appearance of tracheal secretions (absence of pulmonary secretions (score 0), presence of non-purulent pulmonary secretions (score 1), presence of purulent pulmonary secretions (score 2).

Each subscale is scored between 0 and 2, and the total score is 12. In this model, scores ≥ 6 at the baseline or after the entry of microbiological results were considered pneumonia.

Chlorhexidine gluconate mouthwash 0.2% (Behsa Pharmaceutical Co.) was used in the chlorhexidine group. In the chamomile group, chamomile solution (10% Matricaria Chamomila) (Adonis Gol Darou Co.) prepared from the flower of the plant was used according to the opinion of a counseling expert.

In both groups, the patients were placed in the supine position during each intervention, and if there is no prohibition, the head of the bed was raised by 30° and the face was placed to one side. Before performing oral care to ensure the suitability of occlusive endotracheal tube cuff pressure, it was set at 20-25 cmH_2O using a pressure manometer. The intervention was started using a soft pediatric toothbrush soaked with the desired mouthwash and all surfaces of the mouth including teeth and gums per quarter, tongue, inside of the cheeks, hard palate, and soft palate, and the endotracheal tube was brushed. Moreover, 2.5 cc chlorhexidine mouthwash 0.2 and 2.5 ccs chamomile mouthwash were used each time for 30 seconds on each of the aforementioned surfaces and a total mouthwash solution used was 20 cc (10 ccs in the first time and 10 ccs in the second time). The tongue was also brushed gently and away from the end of the tongue. For all patients in both groups, secretions were suctioned and performed at each stage of the intervention, if necessary, and at the end, the lips were cleaned and the mouth became dry. The endotracheal tube was removed and cleaned and placed in the patient's mouth again, the endotracheal tube strip was replaced and some Vaseline was swabbed to lubricate the mucosal surfaces and lips, and then the patient was returned to a comfortable previous state. It took a total of 6 minutes to perform the whole process of oral cleaning and rinsing in both stages. In addition, aseptic tips such as thorough and frequent hand washing and disinfection were observed by the researcher before, during, and after the intervention, and the use of examination gloves when rinsing the mouth and suctioning secretions.

Mouthwashes were used in both groups twice a day for 12 days. At the time interval between mouth-washing interventions, patients' mouth was rinsed with normal saline every 2-3 hours and was suctioned, if necessary. All patients were assessed on the fifth day after the intervention, based on the clinical lung infection assessment checklist that includes the following sections: 1. Temperature control with mercury thermometer (axillary temperature was measured in all patients due to intubation) 2. WBC was performed by CBC test. 3. Oxygenation which was measured by measuring arterial blood gases and pulse oximetry. 4. Chest radiograph was performed by a portable device and seen by an anesthesiologist. 5. Pulmonary secretions were cultured using sterile gloves and a special container by a researcher and another nurse to maintain the sterility of the procedure. 6. Examination of pulmonary secretions for presence or absence, purulence or non-purulence of endotracheal secretions.

The intervention duration was the same for patients in both groups and was performed by the researcher at an interval of 12 hours.

The collected data was entered into SPSS ver. 22 for data analysis. P-value <0.05 was considered the significance level. Independent t-test was used to compare the mean of quantitative variables between the two groups, such as age, and Chi-square and Fisher's exact test were also used to compare the frequency of qualitative variables between the two groups, such as comparing the mean frequency of positive endotracheal and oropharyngeal cultures.

RESULTS

The present study was performed on 80 ICU patients undergoing mechanical ventilation in chlorhexidine and chamomile groups (n= 40 people). There was no statistically significant difference between the two groups in terms of their mean age. The mean age was 39.85 ± 9.55 and 45.10 ± 9.29 years in the chlorhexidine and chamomile groups, respectively. There was also no statistically significant difference between the two groups in terms of the frequency distribution of sex, cause of hospitalization, marital status, place of residence, and insurance status (p> 0.05).

Regarding the prevalence of VAP, the results showed that most participants in the chamomile group (75%) did not have pneumonia and the chlorhexidine group suffered from this complication in 77.5% of cases. The Chi-square test showed statistically significant differences between the two groups in terms of the absence and presence of pneumonia (p = 0). Also, the odd ratio of developing pneumonia in the chamomile mouthwash to chlorhexidine mouthwash was 0.30%. In other words, the risk of pneumonia in the chamomile group was reduced by 30% compared to the chlorhexidine group, and chamomile reduced the risk of pneumonia by up to 70% (Table 1).

Table 1: Distribution of absolute frequency and frequency percentage of subjects in terms of presence and absence of pneumonia in chamomile and chlorhexidine groups

Pneumonia	Number(%)		Z score	p-value
	Cm	Ch		
Presence	10 (25%)	31 (77.5%)	<0.001	22.06
Absence	30 (75%)	9 (22.5%)		

Cm – Chamomile, Ch - Chlorhexidine

The most common microorganism in tracheal culture was Pseudomonas (12.5%) in the chamomile group and Enterobacter (27.5%) in the chlorhexidine group. There was also no microorganism in the tracheal culture of the chamomile group in 75% of cases. The Chi-square test showed statistically significant differences between the two groups in terms of the frequency of microorganisms (Table 2).

Table 2: Absolute frequency distribution and frequency percentage of research subjects in terms of microorganisms in chamomile and chlorhexidine groups

Microorganism	Number (n, %)		Z score	p-value
	Cm	Ch		
Enterobacter	2 (5)	11 (27.5)	26.29	0
Pseudomonas	5 (12.5)	6 (15)		
Klebsiella	0 (0)	7 (17.5)		
Aureus	1 (2.5)	2 (5)		
E-coli	1 (2.5)	3 (7.5)		
Acinetobacter	1 (2.5)	2 (5)		
Absence of microorganisms	30 (75)	9 (22.5)		

Cm – Chamomile, Ch - Chlorhexidine

DISCUSSION

The results of the present research show that chamomile mouthwash was more effective than chlorhexidine mouthwash in preventing VAP so that the CPIS was reduced significantly in patients of the two groups on the fifth day (p <0.001) and these differences were statistically significant.

In a study comparing the effects of chlorhexidine and tooth brushing on the prevention of VAP, Samani et al. found no significant difference between chlorhexidine and brushing or both of them in terms of incidence of VAP and they had no advantage over each other in reducing the incidence of pneumonia [32].

In a clinical trial on the effect of providing oral health services (including 0.12% chlorhexidine digluconate) with or without brushing on the incidence of VAP, Lorente et al. found no significant differences between the two groups in terms of incidence of VAP [33]. Khalifazadeh et al. also found that 0.2% chlorhexidine and swab in comparison with toothbrush and chlorhexidine solution had no significant effect on reducing the incidence of VAP in ICU patients [34]. The results of the study performed by Nideelman et al. showed that brushing 4 times a day with 0.2% chlorhexidine was not able to significantly reduce the incidence of VAP [35].

In a study, Salehi et al. reported that chlorhexidine was more effective on the number of oral bacterial colonies than persica and matrica, but matrica was more effective in reducing the number of bacterial colonies than persica [36].

In a study comparing the antifungal and antibacterial effects of persica, matrica, and Iral wax mouthwashes with chlorhexidine in vitro, Atai et al. showed that among herbal mouthwashes, matrica mouthwash had the strongest antimicrobial effects on Streptococcus sanguis, Streptococcus salivarius, Streptococcus sobrinus, Actinomycosis viscosus and Candida albicans [37].

In a study titled "Comparing the effect of chlorhexidine with chamomile and normal saline on oral bacterial colonization, Azimi et al. reported that chlorhexidine was more effective than both chamomile mouthwash and normal saline in reducing oral bacterial colonization, and also none of the mouthwashes was able to remove Staphylococcus aureus, Pseudomonas, Klebsiella, and Acinetobacter [38].

Another study aimed at determining the effect of brushing, chlorhexidine mouthwash, and brushing + and chlorhexidine on the incidence of VAP among patients undergoing mechanical ventilation showed that chlorhexidine reduced early-onset VAP. Brushing + chlorhexidine was not effective. However, chlorhexidine significantly reduced the incidence of pneumonia among patients with baseline CPIS< 6 on the third day, and brushing could not affect CPIS and increase the effect of chlorhexidine, which is not consistent with the results of the present study [26].

The researchers stated that the type of mouthwash solution is probably less important than using a toothbrush to clean the mouth, which has not been addressed in many studies. In the present study, in addition to mouthwash, toothbrushes were used for both groups of patients. Teeth were brushed using carefully using a soft children's toothbrush soaked in mouthwash. All surfaces of the mouth, gums, tongue, throat, and teeth were brushed. Moreover, all of the areas of the mouth, including both interior and exterior surfaces of the teeth (rotational movements), gums, and tongue (back and forth movements) were brushed. Brushing has a great effect on preventing plaque formation. In this regard, Estaji et al. conducted a study aimed at comparing the effect of chlorhexidine solution and toothbrush in the prevention of oral lesions of 30 ICU patients undergoing endotracheal intubation.

The results showed that toothbrushes and chlorhexidine are effective in the prevention of oral lesions, but a better improvement was observed in oral health in cases where toothbrushes have been used [39].

CONCLUSION

Considering the results of the present study and other relevant studies, we conclude that the use of toothbrushes with mouthwash may reduce the incidence of VAP to some extent directly or indirectly by acting on oral pathogens, however, it still cannot prevent its incidence. This may be because several factors are involved in the development of pneumonia in these patients. For example, there is a significant relationship between GCS< 9 and the incidence of pneumonia [14,40]. There are several other factors many risk factors for VAP in ICUs such as observing other aspects of care such as hand washing, open suction, patients with different immune systems, and the presence of resistant pathogens. Therefore, the limitation of the present study was the lack of control over all these aspects of care due to the limited time and small sample size.

Therefore, considering the advantages of herbal compounds over chemical compounds, the positive effect of chamomile as a mouthwash in critically ill or anesthetized patients can be considered a suitable alternative to chlorhexidine. However, there is a need to further studies on the effect of chamomile mouthwash, especially in the prevention of pneumonia among ventilator-dependent critically-ill patients.

According to the results of the present study, chamomile mouthwash was more effective than chlorhexidine mouthwash on the incidence of VAP in ICU patients and according to the benefits of herbal compounds, chamomile mouthwash can be considered a suitable alternative to chlorhexidine.

Comparison of the effect of intravenous ketamine and midazolam as a premedication in children undergoing cochlear implantation at the time of separation from parents

Abasali Delavari[1], Seyed J. Madani[1], Abbas Rahmani[1], Marzieh Lak[1]

Abstract: *Background and aim: Preoperative anxiety and fear of separation from parents are some of the most important preoperative problems for children with deaf muteness. Here, the effect of intravenous administration of ketamine and midazolam was compared on sedation in children who candidates for choral cochlear implantation at the time of separation from parents.*

Patients and methods: This double-blind, prospective clinical study was performed on 74 children with deaf-muteness before cochlear implantation. Patients were randomly divided into two groups, midazolam (0.1 mg /kg) and ketamine (1 mg/kg). The sedation anxiety score scale (SASS) form was filled in to assess the anxiety and sedation status for each child. The children's relaxation score from recovery was assessed by the PACU sedation score scale (PACUSSS).

Results: The average of the children's anxiety score after the injection of both drugs during the separation from their parents was 3, and there was no significant difference in the mean of SASS between the two groups ($p>0.05$). The mean PACU sedation score scale in both ketamine and midazolam groups was 1.08 ± 0.89 and 1.32 ± 1.01, respectively ($p = 0.27$). The mean of extubation and recovery times in the ketamine group were 10.44 ± 4.47 and 30.27 ± 6.87, respectively, while the mean extubation and recovery times in the midazolam group were 11.83 ± 3.33 and 29.81 ± 6.31 minutes, respectively.

Conclusion: Both ketamine and midazolam caused equal sedation scores in children with deaf muteness at the time of separating from their parents.

Keywords: *deaf-muteness children, cochlear implantation, ketamine, midazolam, sedation, anxiety*

INTRODUCTION

According to the world health organization (WHO), more than 250 million people worldwide suffer from disabling hearing loss and 34 million of which are children [1, 2]. Pediatrics hearing loss, which often results from genetic defects, can be associated with multiple problems. Children with hearing impairment not only have difficulty talking, but also they do not respond to sounds [2]. Therefore, early diagnosis and treatment of this complication are very important for the disease improvement and quality of their life.

Cochlear implantation remains the only reliable therapeutic option for patients with hearing loss and deaf-mutism [3, 4]. However, this surgery is time-consuming and requires general anesthesia which may be associated with

emergence agitation, restlessness, disorientation, and anxiety in children [5, 6]. Deaf-muteness children like healthy children recognize environmental events and preoperative anxiety and the fear of separation from parents are some of the most important preoperative problems for these children [5, 7]. Therefore, sedation or premedication is often needed for deaf-muteness children during their separation from parents and entrance to the waiting room.

Midazolam and ketamine are commonly used as premedication in children undergoing medical procedures [8]. Midazolam is an imidazole benzodiazepine that has depressant effects on the central nervous system and provides sedation, muscle relaxation, and amnesia before procedures [9, 10]. It has a rapid onset of action following oral, intravenous, intramuscular, nasal, and rectal administration [10]. A great number of studies have used midazolam as a safe premedication without any serious adverse effects for sedation of children during procedures [11, 12]. It has been also shown that preoperative oral midazolam reduces separation anxiety and emergence agitation in children following anesthesia [6].

Ketamine is a general anesthetic with sedative and analgesic properties which is commonly used as a premedication for sedation in children [13]. Its favorable effects on cardiovascular and pulmonary parameters are a reason by which physicians use this drug as a sedative [14, 15]. Therefore, these data indicated that both midazolam and ketamine are safe effective sedative premedication agents which can be used in children undergoing painful producers [16]. Although many studies have investigated the effect of midazolam and ketamine for sedation of children following medical surgery, no study evaluated the preoperative effect of these drugs on sedation in children with hearing loss and deaf mutism. Therefore, we designed this study, for the first time, to compare the preoperative effect of midazolam and ketamine as premedication on sedation in deaf-mutism children during their separation from parents and before cochlear implantation.

PATIENTS AND METHODS

Patients

This double-blinded, prospective clinical trial study was conducted on 74 children with deaf-muteness who were referred to Baqiyatallah Hospital for cochlear implantation from June 2019 to November 2019.

This study was registered in the Iranian Registry of Clinical Trials under no. IRCT20161022030421N3 cod. The protocol of the study was confirmed by the ethics committee of Baqiyatallah University of Medical Sciences (IR.BMSU.REC.1397.031).

Written informed consents were signed by all parents. A questionnaire containing demographic data of all patients (e.g. age, sex, weight, and history of any previous illness) was filled before surgery. Children aged from 6 months to 5 years old, and American Society of Anesthesiology (ASA) Class I and II were included in the study. Children who met the following criteria were excluded from the study: (i) sensitivity to ketamine or midazolam, (ii) history of treatments with neuropsychiatric drugs, (iii) age less than 6 months, (iv) increased intracranial pressure (ICP), (v) history of seizure, and (vi) history of chronic diseases such as diabetes, liver disease, and upper and lower respiratory tract infection.

Intervention and measurements

After preliminary considerations and patient selection based on inclusion and exclusion criteria, using a computer-generated randomization list, children were divided into two groups of midazolam (n=37) and ketamine (n=37). Intravenous (IV) access was performed using local anesthetic cream 1 hour before their admission in the operating room. The sedation anxiety score scale (SASS) questionnaire was filled out by an observer who was unaware of the study groups. The questionnaire was filled out based on children's behavior in the pre-operative preparation room when they were with their parents. The SASS score ranged from 1 to 5 based on the child's status (Table 1).

Table 1: The SSAS scoring questionnaire

Score	Status	More details
1	Unconscious	Sleepy, no response to mild motor stimulations
2	Sleepy	Sleepy, may have closed eyes but react to mild stimulations
3	Normal	Calmly, comfortable sited or sleeping with eyes open
4	Anxious	Looks afraid, no adhesion to parents, without crying
5	Very rest less	Crying, stomping, or adhesion to parents

After SASS scoring, midazolam (0.1 mg/kg) or ketamine (1 mg/kg) drugs were intravenously injected into children by another person who was unaware of the study groups. Following the injection of the drug, pulse oximetry monitoring was provided for patients. Furthermore, the SASS form was filled out again following the drug's injection just after children felt calming and when they were separating from their parents. Children were then transferred to an operating room and the observer measured the extent of child tolerance during the anesthetic induction by SASS.

Pethidine (1 mg/kg) and atropine (0.2 mg/kg) were injected into children as premedication and then anesthesia induction was performed with propofol and atracurium. Sevoflurane was applied to maintain the anesthesia. Cefazolin, hydrocortisone, and dexamethasone were injected into all children. All children also received ondansetron (1 mg/kg). Children were transferred to the recovery room after surgery and the observer assessed the sedation rate by the post-anesthesia care unit (PACU) sedation score scale (PACUSSS) (Table 2). The PACUSSS score ranged from 0 to 4 based on the child's status. When children obtained the safe discharge criteria from the recovery room, they were transferred to the section. The observer also recorded any postoperative side effects or complications such as nausea, vomiting, emergence agitation, and decreases in arterial oxygen saturation below 92%. The duration of surgery, extubation time, and recovery time was also recorded.

Table 2: The PACU sedation score scale questionnaire

Score	Status
0	Slept, calmly, and without crying
1	Whining, Not rest less
2	Crying, Slightly rest less
3	Continuous crying

Statistical analysis

The results of this study were analyzed by SPSS software (IBM, version 19). Quantitative data were analyzed using the descriptive program and presented as Mean ± SD. Crosstabs and Chi-Square tests were used to compare the percentages or frequencies between the two groups. The comparison of the mean of parametric data between midazolam and ketamine groups was compared by independent student samples-test. In this study, p< 0.05 was considered statistically significant.

RESULTS

In this study, 74 patients were entered into the survey. 32 patients were boys (43.2%) and 42 patients (56.8%) were girls. There was no significant difference in the percentage of male and female genders between midazolam and ketamine groups (p=0.24; Table 3).

The mean age of all participated patients was 29.55 ± 16.92 months. There was no significant difference in the mean age of patients between the ketamine and midazolam groups (p=0.94; Table 3).

The mean weight of all participated patients was 13.18 ± 3.74 kg. There was no significant difference in the mean weight of patients in the ketamine and midazolam groups (p=0.72; Table 3).

Table 3: Demographic characteristics of patients in both groups

Parameters	Midazolam	Ketamine	p-value
Age (months)	29.7 ±17.68	29.4 ±16.36	0.94
Gender			
Male (%)	18 (48.64%)	14 (37.83%)	0.24
Female (%)	19 (51.35%)	23 (62.16%)	
Weight (kg)	13.33 ± 4.3	13.02 ± 3.13	0.72

A comparison of the mean of SASS between the ketamine and midazolam groups is shown in Table 4. There was no significant difference in the mean of each score between the two groups. The mean score of children status in the waiting room with their parents was approximately 4, indicating they were anxious. The mean score of children's status after drug injection, when separating from their parents was decreased to around 3, which suggests the normal status of the patients in both groups. Furthermore, the mean score of the patient’s condition at the anesthetic induction time ranged from 2.5 to 3, which indicates they had sleepy or normal conditions.

Table 4: Comparison of the mean of SASS between ketamine and midazolam groups

Parameters	Midazolam	Ketamine	p-value
In the waiting room with parents	4 ± 0.78	3.89 ±0.9	0.58
After drug injection, when separating from parents	2.91 ± 0.49	2.83 ± 0.55	0.5
Anesthetic induction time	2.62 ± 0.68	2.59 ± 0.68	0.86

The prevalence of each SSAS item in the waiting room before pre-medication is presented in Table 5. There was no significant difference in the frequency of each item in patients between the two groups (p=0.6). Most of the children (40.54% in the ketamine group and 48.64% in midazolam groups) had the anxious condition before premedication. Furthermore, 27.02% of children in the both ketamine and midazolam groups were very restless. The percentage of normal conditions in children in the midazolam and ketamine groups was 21.62% and 29.72%, respectively.

The prevalence of each SSAS item after drug injection, when separating from their parents is presented in Table 5. No significant difference was found in the frequency of each item between the two groups (p=0.68). Most of the patients (67.56% in the ketamine group and 75.67% in midazolam groups) had the normal condition. 24.32% of children in ketamine and 16.21% of patients in the midazolam group were sleepy. Only 8.1% of patients in both groups had anxiety conditions.

The percentage of each SSAS item at the time of anesthetic induction is shown in Table 5. There was no significant difference in the frequency of each item between the two groups (p=0.69). Most of the patients (54.05% in the ketamine group and 48.64% in midazolam groups) had the normal condition at the time of anesthetic induction, while 40.54% of children in ketamine and 45.94% of patients in the midazolam group were sleepy. Only 2.1% of patients in both groups were very resting less.

Table 5: The prevalence of pediatrics SSAS in different conditions

Parameters	Midazolam	Ketamine	p-value
Before pre-medication			
Unconscious	0	1 (2.7%)	
Sleepy	1 (2.7%)	0	
Normal	8 (21.62%)	11 (29.72%)	0.6
Anxious	18 (48.64%)	15 (40.54%)	
Very rest less	10 (27.02%)	10 (27.02%)	
Separating from parents			
Unconscious	0	0	
Sleepy	6 (16.21%)	9 (24.32%)	
Normal	28 (75.67%)	25 (67.56%)	0.68
Anxious	3 (8.1%)	3 (8.1%)	
Very rest less	0	0	
Anesthetic induction time			
Unconscious	0	1 (2.7%)	
Sleepy	17 (45.94%)	15 (40.54%)	
Normal	18 (48.64%)	20 (54.05%)	0.69
Anxious	1 (2.7%)	0	
Very rest less	1 (2.7%)	1 (2.7%)	

The prevalence of children's relaxation scores during the recovery time can be seen in Table 6. There was no significant difference in the prevalence of children's condition between the two groups (p=0.64). Most of the patients (37.83% in ketamine and 32.43% in midazolam groups) had to whine without rest less, whereas 29.72% of patients in ketamine and 24.32% in midazolam groups were kept without crying. Only 5.4% of children in ketamine and 13.5% in midazolam were continuously crying.

Table 6: The prevalence of children relaxation scores during the recovery time

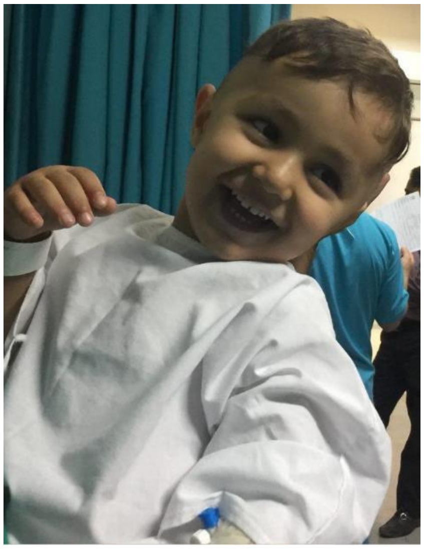
Children status	Midazolam	Ketamine	p-value
Slept, calmly and without crying	9 (24.32%)	11 (29.72%)	0.64
Whining, Not rest less	12 (32.43%)	14 (37.83%)	
Crying, Slightly rest less	11 (29.72%)	10 (27.02%)	
Continuous crying	5 (13.51%)	2 (5.4%)	

There was no significant difference in the mean of extubation (p=0.2) and recovery times (p=0.76) between the two groups. The mean of extubation and recovery times in the ketamine group were 10.44 ± 4.47 and 30.27 ± 6.87 minutes, respectively, while the mean extubation and recovery times in the midazolam group were 11.83 ± 3.33 and 29.81 ± 6.31 minutes, respectively.

We didn’t observe any significant side effects from both studies' drugs. In the waiting room, no child showed a drop in SPO2 below 92% and there was no need for mask ventilation for these patients. Nausea and vomiting were the most important complications after recovery. Three patients (8.1%) in the ketamine group had nauseous and 10 (27.02%) in the midazolam group suffered from nausea (p=0.023). Also, one patient in the midazolam group had vomiting. None of the patients in both groups experienced emergence agitation and decreased arterial oxygen saturation in recovery time.

Interestingly, our findings showed that 37.03% of children in the midazolam group start laughing after receiving premedication (Figure 1), but this condition was not observed in patients in the ketamine group.

Figure 1: Children's reaction after premedication with midazolam. About 37% of children in the midazolam group start laughing after receiving this premedication, but this status was not observed for children in the ketamine group



DISCUSSION

In this study, we compared the intravenous administration effect of ketamine and midazolam as a premedication in children undergoing cochlear implants at the time of separating from their parents. To the best of our knowledge, the use of intravenous midazolam and ketamine for sedation of children with deaf-muteness before cochlear implantation has not been investigated yet. Our data have revealed that there was no significant difference in the mean anxiety score between the ketamine and midazolam groups. Children were anxious (mean sedation anxiety score of 4) before premedication with ketamine and midazolam, while they reached normal status (mean sedation anxiety score of 3) after premedication. Furthermore, most children had sleepy and normal status after premedication at the time of anesthetic induction. There was no significant difference in the mean PACU sedation score between the ketamine and midazolam groups. Furthermore, we didn’t find any serious adverse effects in each group; however, nausea occurred more frequently in the midazolam group. More importantly, we found that 37.03% of children in the midazolam group started laughing after receiving the premedication, while this condition was not observed in patients in the ketamine group. However, this mechanism is unclear.

A great number of studies compared the effect of ketamine and midazolam as premedication in the prevention of anxiety, pain score, and emergence agitation in children and adults before entering the operating room. For example, Jeong et al. [17] demonstrated that intravenous administration of ketamine (1 mg/kg) before entering the operating room significantly reduces separation anxiety, postoperative pain score, and also the incidence of emergence agitation in children following ophthalmic surgery. Ozdemir et al. [18] reported that intravenous, oral, and rectal administration of ketamine and midazolam had equal sedation effects in children with malignancy. Several studies compared the combination of ketamine and midazolam as premedication in different groups. For example, Golpayegani et al. [19] compared the oral administration of ketamine and midazolam as sedative agents in pediatric dentistry. They found that the Ketamine-Midazolam combination provides sufficient sedative effect in children's behavior. In another study, Wathen et al. [20] found that intravenous ketamine and its combination with midazolam had equal effective sedation in children. They also found that vomiting occurred more frequently in the ketamine group, while oxygen desaturation occurred more frequently in the ketamine-midazolam group. Barkan et al. [21] evaluated the efficacy of oral midazolam alone and oral midazolam-ketamine combination in 60 children requiring laceration repair. They didn’t find a significant difference in the mean pain score between the two groups; however, midazolam and ketamine combination caused deeper sedation than midazolam alone. Additionally, no clinically significant adverse effects were found in either group which was in agreement with the results of our study. In another study, the effect of high dose oral ketamine (10 mg/kg) with midazolam (0.7 mg/kg) was evaluated in children during laceration repair [12]. The results showed better tolerance to local anesthetics and deeper sedation in children treated with ketamine with no serious adverse events in both groups [12]. Kim et al. [6] investigated the intravenous effect of ketamine (1 mg/kg) and midazolam (0.1 mg/kg) on emergence agitation in children at the postanaesthetic care unit. They showed that premedication with these drugs significantly decreases preoperative anxiety. However, they found that premedication with ketamine was more effective than midazolam in the prevention of early post-operative emergence agitation. Similarly, in this research, we used the same doses of ketamine and midazolam for the improvement of preoperative anxiety and sedation in children. Our data showed that premedication with ketamine and midazolam significantly improves anxiety and sedation in children without any serious side effects.

Our findings have also revealed that there is no significant difference in the mean of extubation and recovery times between the two groups. Similarly, Kim et al. [6] didn’t found a significant difference in the mean of extubation and recovery times between children in midazolam and ketamine groups. Ozdemir et al. [18] reported that ketamine and midazolam are equally effective in recovery time improvement. Recent evidence has proposed that the recovery time in patients receiving ketamine and midazolam is dependent on multiple factors such as drugs dosage, kind of surgery, and the physician on call. For example, previous studies didn’t observe a significant improvement in recovery times when children were treated with higher doses of ketamine (2.5-3 mg/kg) and midazolam (0.25-0.5 mg/kg). Several studies reported higher recovery times in children treated with higher doses of midazolam (0.5 mg/kg) and ketamine (5 mg/kg) [21]. Abdolahi et al. [22] reported that low dose administration of ketamine (0.5 mg/kg) during anesthesia induction did not affect postoperative pain score, postoperative nausea, and vomiting, as well as perioperative additional analgesic requirements in ophthalmic surgery. However, premedication with ketamine improved the extubation time. Based on these data, in our study, children were treated with 0.1 mg/kg midazolam and 1 mg/kg ketamine. Therefore, these data suggest that both drugs are equally effective for the prevention of anxiety in children before surgery and separating from their parents. However, the dose of drugs and kind of surgery are important factors affecting sedation and anxiety which should be considered before administration.

CONCLUSION

In summary, the results of the current clinical study indicated that both midazolam and ketamine are equally safe with desirable sedation effects on children with deaf-muteness before separating from their parents for cochlear implantation. Premedication with 0.1 mg/kg midazolam or 1 mg/kg ketamine decreases preoperative anxiety in these cases. Both drugs improved recovery and extubation times without any serious adverse effects. However, nausea occurred more frequently in the midazolam group. More importantly, children in the midazolam group start laughing after premedication with this drug which caused their parents felt well, while children in the ketamine group didn’t show this reaction. Further studies with a larger sample size should be conducted to determine the optimal dose and to establish the safety of the combination therapy.

Acknowledgments

We would like to express our thanks to all members of the anesthesiology department, Baqiyatallah hospitals, Tehran, Iran for the essential contribution. This study was supported by a grant provided from the Department of Anesthesiology, School of Medical Sciences, Baqiyatallah University of Medical Sciences (Tehran-Iran).

VARIA

Compliance of school doctors' practice with medical legislation

Silviu Paun[1], Luiza M. Vasile[2], Sinziana Birsanu[3], Codrut A. Nanu[1]

Abstract: *School doctors' practice comprises specific aspects governed by legal rules. Knowledge and compliance with the applicable legislation are necessary in order to ensure respect of the patient's rights, to avoid claims of medical malpractice and to assure medical act's quality.*

The present study investigated compliance of school doctors' practice with the applicable legal requirements.

All respondent doctors violate the applicable legal requirements. Future quantitative research is necessary to measure the amplitude of the identified vulnerabilities.

INTRODUCTION

School doctors' assistance implies ensuring special conditions for children with chronic diseases, coordinating the optimal response during medical emergencies and managing school environment's health and safety.

Sports competitions for students represent another special feature in this field, given the school doctor's task of issuing a favourable notice for competition to students who participate in such competitions following a brief clinical examination, without always having the student's personal background checks or the possibility to send the student to a specialist for control, without having an appropriate emergency kit and under improper conditions for a medical act which can all generate problems related to malpractice.

Specific aspects of their activity expose them in case of ignorance and non-compliance of the applicable legal regulations.

RESEARCH OBJECTIVE

The assumption under which our research was initiated was that school doctors from Bucharest are not fully aware and do not fully comply with the legislation in force.

The research objective was to collect information regarding the compliance of school doctors' practice with the applicable legal requirements.

MATERIAL AND METHOD

The present research aimed to identity the existence of a phenomenon (the issue regarding compliance of school medical activities with the applicable legal provisions) and to establish the framework for possible future quantitative research addressed to the newly developed area of interest.

The target group included 25 general practitioners activating as school doctors in Bucharest. Sample was selected taking into account the qualitative objects of the research, in the sense that we aimed to identify possible specific tendencies among school doctors. The investigative techniques were represented by interviews, which led to structuring of a questionnaire comprising five closed questions destined to evaluate the risk of malpractice in the school doctors'

[2] "Carol Davila" University of Medicine and Pharmacy, Faculty of Medicine, Bucharest, Romania
[3] Bucharest Bar, Lawyer

activity. Developed models because of previous research in the field of knowledge and compliance with medical legislation by doctors were used when preparing the questionnaire.

The questionnaires were then circulated and filled in anonymously during a workshop organized by the Administration of Hospitals and Medical Services Bucharest (Administrația Spitalelor și Serviciilor Medicale București - ASSMB) and which took place in Bucharest, on 8.12.2017.

Participants were asked to answer the questions based on their daily practice and not on theoretical knowledge or personal opinions regarding the respective matters.

Moreover, respondents were informed that their answers would be used exclusively for scientific purposes, for performing an objective valuation of the malpractice risk resulting from non-compliance with the legal framework applicable to school doctors' practice.

Definition of the valuation criteria for answers to the questionnaire's inquiries

Thus, the interviews aimed to investigate if medical practice of respondent doctors respects the applicable legislation.

The doctors' answers were marked as "correct" if they indicated the fact that the practice of the respondent doctor respects the legal requirements involved by the question or "wrong" when the answer demonstrated non-compliance of the law by the respondent doctor during his daily medical activity.

In addition, the alternative answers selected by respondent doctors were analysed in detail with the purpose of identifying some models of practice and their justifications. Programme IBMSPSS Statistic, version 20 was used for processing the obtained data.

RESULTS AND DISCUSSION

General results

None of the respondent doctors chose the "correct" answer to all the questions. Therefore, we can consider that, in their current activity, respondent doctors do not fully respect the legal framework applicable to school doctors.

Specific results

Based on received answers we identified some domains of medical practice in which specific legal requirements are not fully respected: informed consent, confidentiality of medical data, patients' access to personal medical information, filming/photographing of patients and limiting the doctor's activity to one's own medical specialty.

Question no. 1

"How do you proceed when a patient requires health care for an associated disorder beyond the scope of competence of your specialty?"

Proposed alternatives to answer:
a) I do not provide health care, regardless the patient's status.
b) I provide health care after consulting a specialized doctor in the field of the respective disorder.
c) I provide health care in emergencies.

The correct answer (to be chosen between the proposed alternatives) is: c)

The general representation of answers to Question no. 1 is included in Table 1 and Chart 1.

Chart 1: Representation of answers to Question no. 1, according to valuation: correct/wrong.

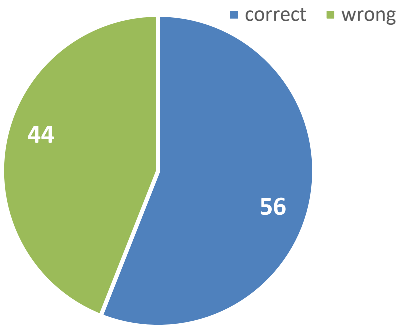

Table 1: Answers to Question no. 1

		Frequency	Percent	Valid percent	Cumulative percent
Valid	a	1	4.00	4.00	4.00
	b	4	16.00	16.00	20.00
	b, c	5	24.00	24.00	44.00
	c	14	56.00	56.00	100.00
	Total	25	100.00	100.00	

It may be noticed that 44% of answers were wrong. In order to identify the respondent doctors' attitude concerning limiting the medical practice to its own specialty we performed a detailed analysis of the received answers to each question, the results being included in Table 1 and Chart 1.

The correct action for the situation described by this question from the questionnaire is prescribed by legal texts: the medical practitioners are civilly liable for the damages caused during the exercise of their profession and when they exceed the limits of their competence. In case of some associated disorders', each of these conditions will have to be supervised/diagnosed/treated by a doctor specialized in the respective area of expertise/competence. Therefore, the legislation includes an interdiction for doctors to perform medical acts that are not covered by their specialty.

There is an exception to this rule in case of emergencies when there is an imminent danger/irreversible deterioration of patient's health state and when a medical practitioner with the necessary competence is not available. [3]

It may be noticed that 24% from respondents included the correct alternative c), but they also added alternative b) (which is wrong), while 16% from respondents mentioned only alternative b) as being correct.

The attitude of respondent doctors is to provide health care beyond their specialty in every situation after they ask a medical practitioner having the necessary area of expertise. These attitudes do not comply with the abovementioned legal requirements.

In situation when all 3 conditions are cumulatively met (urgency, imminent danger for patient's life/irreversible deterioration of patient's health state, lack of specialized medical practitioners) medical activities beyond one's area of expertise can be performed without the need to consult another medical practitioner.

Question no. 2

"*Can information regarding the treatment prescribed to a patient be communicated to third parties?*"

Proposed answers:
a) Yes, to non-governmental organizations which support the patients.
b) Yes, to patient's family members.
c) No.

The correct answer (to be chosen from the proposed alternatives) is: c).

According to the law, the doctor cannot disclose to any other person than the patient data regarding its health state. Information concerning patient's status, results of medical investigations, diagnosis, prognosis, treatment and personal data are confidential, even after the patient's death.

General representation of answers to Question no. 2 is included in Table 2 and Chart 2.

Wrong answers were generated by the doctors' attitude to communicate medical data to patient's family members. It may be supposed that doctors chose this answer given the fact that patients' majority (with the exception of students) are minors.

Chart 2: Representation of answers to Question no. 2, according to valuation: correct/wrong

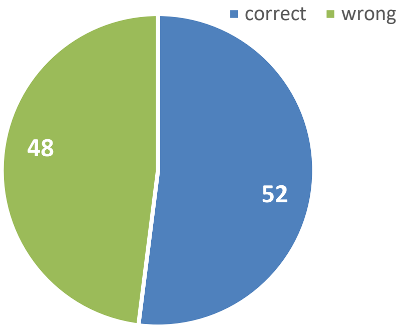

Table 2: Answers to Question no. 2

		Frequency	Percent	Valid percent	Cumulative percent
Valid	b	12	48.00	48.00	48.00
	c	13	52.00	52.00	52.00
	Total	25	100.00	100.00	

However, the question did not refer to minor patients. Even if we referred to minor patients, not every family member is a legal representative (there are various circumstances prescribed by law in which parents, relatives, other people can be legal representatives for a minor patient). Therefore, not even under this scenario, the alternative b) would have been correct. This represents more a vulnerability of respondent doctors' practice with respect to compliance of medical practice with the abovementioned legal requirements.

Question no. 3

"*The informed consent of the patient may be obtained*:"

Proposed answers were the following:
a) From the patient attaining the age of 18.
b) From a minor patient under some circumstances.
c) From one of the minor patient's parents.

Correct answer to this question: a), b), c).

According to law, the statutory age for giving an informed consent is 18.

Minor patients may give their consent in absence of parents or legal representative, in medical situations related to the diagnosis and/or treatment of sexual and reproductive problems, when specifically requested by a minor patient who is over 16 years old.

The important amount of wrong answers (96%) requires an in-depth analysis of answers to this question.

Chart 3: Representation of answers to Question no. 3, according to valuation correct/wrong

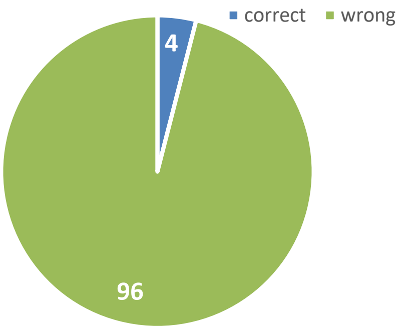

Table 3: Answers to Question no. 3

		Frequency	Percent	Valid percent	Cumulative percent
Valid		1	4.00	4.00	4.00
	a	3	12.00	12.00	16.00
	a, b, c	1	4.00	4.00	20.00
	a, c	20	80.00	80.00	100.00
	Total	25	100.00	100.00	

80% from respondent doctors only selected two of the three correct answers. Therefore, the legal prescription, which allows obtaining an informed consent from minor patients, which are at least 16 years old for sexual and reproductive problems, is not known and respected. Surprisingly, 12% of respondents did not identify the answers as being applicable to medical practice given the fact that these people consider that it is mandatory to obtain the informed consent from both parents of a minor patient.

Question no. 4

"Should medical data concerning undertaken investigations, established diagnosis and recommended treatment be made available to the patient?"

The proposed alternatives to answer:
a) It is not necessary; when discharging the patient from hospital, the treatment scheme and the necessity to come back for control should be explained to the patient.
b) Yes, always, in a complete manner.
c) Information related to diagnosis and established treatment should be made available to the patient"

The correct answer (to be chosen from the proposed alternatives) is b).

According to law no. 46/2003, the patient has unlimited access to all personal medical information and the doctor has to make it available to the patient and, in writing, if the patient requests it.

Almost half of respondent school doctors (44%) do not ensure unlimited access to personal medical information for patients/legal representatives.

Chart 4: Representation of answers to Question no. 4, according to valuation correct/wrong

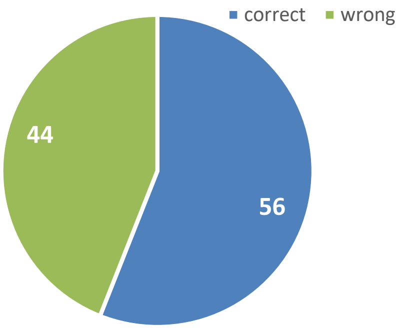

Table 4: Answers to Question no. 4

		Frequency	Percent	Valid percent	Cumulative percent
Valid		1	4.00	4.00	4.00
	b	15	60.00	60.00	64.00
	b, c	3	12.00	12.00	76.00
	c	6	24.00	24.00	100.00
	Total	25	100.00	100.00	

The analysis of chosen answers demonstrates that 24% from doctors consider that only information regarding diagnosis and treatment must be made available to the patient/legal representative.

This attitude may also be caused by an excess of legislation, which generates confusion. Thus, law no. 46/2003 was amended in 2016, the following article being added: "Article 12: the patient or the person expressly designated by the patient, according to articles 9 and 10, has the right to receive, when discharged from hospital, a written summary of investigations, diagnosis, treatment, medical care provided during hospitalisation and, upon request and once, a copy of high performance investigations' records.".

It may be generated the impression that information mentioned in this article could be accessed only by patients, but this interpretation would contradict article 9 of the norms for application with respect to Law no. 46/2003 regarding patient's rights which prescribes the following: "the hospital units must ensure unlimited access to personal medical data for patients ".

We believe that medical practice should take into account the most restrictive (unlimited access) legal requirement and this represents a correct attitude for a school doctor,

Question no. 5

"*May the medical personnel film the patient in the medical unit?*"

The proposed answers were the following>
a) After obtaining the patient's written consent.
b) By protecting the patient's identity.
c) For teaching and research purposes exclusively.

The correct answer (to be chosen from the proposed alternatives) is b).

The patient cannot be photographed or filmed in a medical unit without his consent, with the exception of the situation when the images are necessary for diagnosis and treatment and for avoiding the suspicion of medical malpractice.

Therefore, the medical personnel may film/photograph without the patient's or the legal representative's consent if the confidentiality of data which is obtained throughout this means is protected.

Chart 5: Representation of answers to Question no. 5, according to valuation correct/wrong

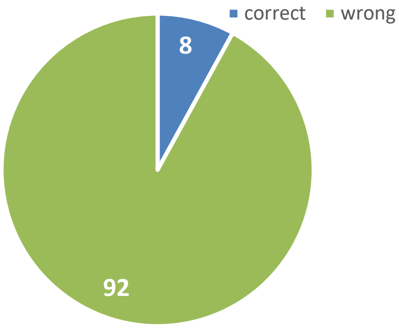

Table 5: Answers to Question no. 5

		Frequency	Percent	Valid percent	Cumulative percent
Valid		1	4.00	4.00	4.00
	a	11	44.00	44.00	48.00
	a, b	2	8.00	8.00	56.00
	a, b, c	6	24.00	24.00	80.00
	a, c	1	4.00	4.00	84.00
	b	2	8.00	8.00	92.00
	b, c	1	4.00	4.00	96.00
	c	1	4.00	4.00	100.00
	Total	25	100.00	100.00	

Most of wrong answers are generated by respondent doctors' conviction that they need patient's consent for filming/photographing him/her. It may be noticed that there are many alternatives of answers selected for this question that suggests the ignorance of the specific legal framework.

CONCLUSIONS

School doctors' practice does not respect entirely the applicable legal framework.

The consequences are that civil liability may be incurred against doctors and the protections of malpractice assurance ceases. Moreover, respecting patients' rights represents an element to measure medical act's quality, as defined by the National Authority of Quality Management in Health (Autoritatea Naţională de Management al Calităţii în Sănătate – ANMCS) throughout specific accreditation standards for medical units. Extensive further studies are necessary in order to determine this phenomenon's amplitude and configuring some education projects destined to cover the identified educational need is necessary.

Complications of systemic lupus erythematosus: A review

Georgiana Iftimie[1], Anca Pantea Stoian[2], Bogdan Socea[1,3], Ion Motofei[1,3], Dragoș Marcu[1,4], Raluca S. Costache[1,5], Camelia Diaconu[1,6]

Abstract: *Systemic lupus erythematosus (SLE) is a complex autoimmune condition, which often evolves with severe complications. In SLE, autoantibodies appear, with systemic inflammation and multiple tissue destructions. SLE is the most common form of lupus and is considered more severe than other forms. SLE can affect many parts of the body, including the kidneys, heart, lungs, brain, blood, and skin. Symptoms vary among patients. SLE can follow an unpredictable pattern of remissions (symptoms improve) and flares (symptoms worsen). Renal involvement is one of the most severe complications in SLE patients. The process of depositing the immune complexes in the kidneys could lead to the appearance of lupus nephritis. If the treatment is early and treat-to-target, it can change the course of the renal disease.*

Keywords: *systemic lupus erythematosus, renal complications, target treatment*

INTRODUCTION

Systemic lupus erythematosus (SLE) is a complex autoimmune condition, characterized by an exaggerated activity of the immune system, which often evolves with severe complications. In SLE, autoantibodies appear, with inflammation and multiple tissue destructions.

EPIDEMIOLOGY OF SLE

SLE is a disease that appears particularly in young people, aged between 15 and 45 years, mainly young women. 10-15 times more women than men have SLE. The black population is more commonly affected by the disease, 2-3 times more than the white population, and develop more aggressive forms [1]. The incidence of the disease has increased significantly over the last decades, probably due to the development of diagnostic methods. [2]

ETIOLOGY OF SLE

The etiology of SLE includes genetic, environmental, hormonal and immune factors, which have a strong importance in triggering the disease.

Genetic factors plays an important role in triggering SLE. The monozygotic twins` disease risk is about 57% higher compared to heterozygote twins' risk.[3]

The existence of genetic susceptibility is also supported

by the presence of other autoimmune diseases, such as autoimmune thyro-iditis, hemolytic anemia, idiopathic thrombocytopenic purpura [4,5]. SLE is associated with a multigenic determinism. The correlation with the major histocompatibility complex (MHC) on the short arm of the chromosome 6 has a particular importance in the development of the autoimmune processes in SLE [6]. Clinical studies have demonstrated the association of certain haplotypes of HLA DR (DR2 and DR3), DQ (DQ6), B8, components of the complement system (C2 and C4) with various clinical and immunological manifestations. Other genes, like C1q, the Fcγ receptor gene may be involved.

The *environmental factors* involved in the SLE are: ultraviolet rays (UV), that can trigger the autoimmune processes, justifying the occurrence or exacerbation of clinical manifestations after exposure to sun; both viral and bacterial infections: antibodies anti Epstein-Barr virus are present in the serum of SLE patients; bacterial triggers (bacterial DNA, membrane lipopoly-saccharides, endotoxins) were described as factors that can induce an exaggerated immune response; medications that may cause SLE or "lupus-like" phenomena: hydralazine, procainamide, isoniazide, chlorpromazine, methyldopa, penicillamine, minocycline, TNF alpha inhibitors, alpha-interferon; other possible environmental factors: nutritional, vitamin D deficiency, smoking.[7-10]

Hormonal factors: the increased prevalence of the disease in women is supported by increased levels of estrogen and prolactin. Dihydroepiandrosterone has low values in SLE patients.[11] Birth control and substitution therapy hormone increases the risk of developing SLE in the women with a certain genetic susceptibility.[12]

Immune factors. Lymphocytes T and B, monocytes, macrophages and neutrophils have increased production of autoantibodies in SLE patients.[13] The formation of autoantibodies has a central role in the appearance of SLE complications. The main antibodies are antinuclear antibodies (ANA). Anti-DNA antibodies (Ac anti-ADNdc) are the most specific for diagnosis, being correlated with disease' activity. Anti-histone antibodies are associated with drug-induced SLE. Other types of antibodies are: anti-Chromatin; antibodies to RNA structures and ribonucleoproteins; anti Smith antibodies, only described in SLE; antiprotetic P ribosomal antibodies.[14]

Autoantibodies in SLE participate in lesions of various organs through the formation of immune complexes (by immune response of type III) or by the direct action of these antibodies (by type II cytotoxic reaction) [15]. Pathogenic alterations can be secondary to deposition of circulating immune complexes, but also the formation in situ of immune complexes, especially at renal, cutaneous, vascular, nervous system level, causing inflammatory phenomena because of activation of the complement system.[16]

Lupus has different forms: systemic, cutaneous, drug-induced, and neonatal.

The systemic form is the most severe and complex, leading to kidney, heart, lung, brain, blood and skin complications. Symptoms vary among patients. SLE can follow an unpredictable pattern of remissions (symptoms improve) and flares (symptoms worsen).

Cutaneous lupus is a form of lupus that involves only the skin and causes rashes. These rashes may appear anywhere, but are usually found on the face, neck, and scalp. When the cutaneous lesions had an atypical localization, a differential diagnosis is needed [17-19]. This type of lupus usually does not involve the internal organs, but a number of patients living with cutaneous lupus will develop systemic lupus.

Drug-induced lupus can occur after the intake of high doses of certain drugs. The symptoms are similar to systemic lupus, but usually disappear when the drug is stopped or can manifest six months to one year. The antinuclear antibody (ANA) test may remain positive for years.

Neonatal lupus is present in newborns of a woman with lupus or another autoimmune disease. This condition can cause skin rashes, anemia or liver complications. Symptoms usually disappear after a few months and do not cause permanent damage. Some babies with neonatal lupus can be born with a severe heart defect.[18]

COMPLICATIONS OF SLE

SLE is a complex, multifactorial and polymorphic disease that may lead to severe complications.

Muscular complications. Muscular pain, commonly encountered in many diseases, may occur frequently in SLE patients with progressive evolution and it can often lead to a misdiagnose [20,21]. It is often located in the scapular-humeral belt and symptoms like myalgia and muscle weakness often appear.[19] Finally, franc myositis is associated with the increase in serum muscle enzymes, aminotranspherases or creatine kinase levels.[22] The pain is, in many cases, very severe an requires multimodal treatment.

Osteoarticular complications. Arthritis in SLE resembles that of rheumatoid arthritis, symmetrically affecting the small joints of the hands. In the case of SLE, arthritis is non-erosive. A special form of SLE arthritis is Jaccoud arthropathy, with deformations “swan neckline” type. When erosive arthritis occurs in SLE, it is called rhupus. Osteoporosis can occur frequently in SLE patients and is directly related to the high risk of fractures [23]. The surgical management of these fractures is complicated, especially due to bone fragility, needing limited periosteum stripping in order to prevent further damage of the bone [24]. Osteoporosis can also be associated with the adverse effects of cortisone therapy in these patients.

Cardio-vascular complications. The most common are pericarditis, which may range from asymptomatic to accumulation of moderate fluid, and myocarditis, with global hypokinesia at echocardiography.[25] A typical lesion that may occur in SLE patients is Libman-Sacks verrucous endocarditis, with thickening of the mitral and aortic valve [26-28]. The presence of antiphospholipid antibodies appears to be directly related to valvular damage.[29]

Pulmonary complications. Pleural effusion is the most common, is bilateral, and associated with the presence of antinuclear antibodies. In patients with SLE, impairment may be at the level of parenchyma, with lupus pneumonia or alveolar hemorrhage, or at the pulmonary vessels level, with pulmonary hypertension.[30,31]

Gastrointestinal complications may vary from mesenteric vasculitis or intestinal obstruction syndromes to peritonitis, pancreatitis or inflammatory bowel syndromes [32,33]. The most common symptoms are abdominal pain, nausea, anorexia, and vomiting [34,35]. Hepatomegaly and hepatic enzyme elevations are found in 30% of patients, hepatorenal syndrome can appear [36], and Budd Chiari syndrome may also be associated with the presence of antiphospholipid antibodies.[37-39]

Neuro-psihiatric complications are the least understood complications. They may involve either the central nervous system, causing aseptic meningitis, seizures, anxiety syndrome, psychosis, or the peripheral nervous system, with myasthenia gravis, mononeuritis, autonomic neuropathy or polyneuropathy. Endothelial dysfunction may be responsible for the passage of autoantibodies to the nervous system and the occurrence of the lesions.[40]

Renal complications are one of the most serious complications in SLE patients [41-43]. The process of depositing the immune complexes in the kidneys could lead to the appearance of lupus nephritis.[44] The classification of ISN RPS 2004 of lupus nephritis is universally accepted:

- Class I: Minimal mesangial lupus nephritis, with normal glomeruli by microscopic evaluation, but mesangial immune deposits at immunofluorescence.
- Class II: Mesangial proliferative nephritis, with mesangial hyperplasia at the optical microscope, but mesangial immune deposits on immunofluorescence.
- Class III: Focal proliferative nephritis, involving less than half of the glomeruli, with or without mesangial involvement. Subgroups: IIIA (active lesions); IIIA/C (active and chronic lesions); IIIC (inactive lesions).
- Class IV: Diffuse proliferative nephritis, involving more than half of the glomeruli.
- Class V: Membranous nephritis.
- Class VI: Sclerotic nephritis with no active lesions.

Other less common forms of lupus renal disease include interstitial nephritis, drug-induced and vascular disease, when the renal vessels are affected.[40,44,45]

Paraclinical, the parameters evaluated are: 24-h proteinuria, with values above 0.5 g/24 h; active urinary sediment with diffractional red blood cells and cell cylinders; serum creatinine above the upper limit of the laboratory, low creatinine clearance, low complement and high titer of double-stranded DNA antibodies.[46]

Usually, about 25–50% of lupus patients have abnormalities of the renal function, starting early or during the evolution of the disease. The renal complications seem to be discovered in the first three years after the diagnosis of SLE.[47,48] Regarding the ethnic origin, different studies revealed that renal impairment is significantly worse in black subjects than in white patients with lupus nephritis.[49-51]

Proteinuria is considered to be the essential piece in the lupus nephritis structure. In a review on lupus nephritis, proteinuria was reported in 100% of patients, with nephrotic syndrome in 45–65%.[47] Microscopic hematuria was found in about 80% of patients during the disease course.[46]

A recent retrospective study, exploring the determinants of earlier renal disease in patients with SLE, found that features like young age, non-European origin and male sex have a great impact on the disease [52]. Approximately 10–15% of patients with lupus nephritis, despite treatment, progress to end-stage renal failure.[49] Features predictive of end-stage renal disease in patients with severe lupus nephritis included higher baseline serum creatinine level and failure to obtain remission, with increased level of potassium, which can lead to arrhythmic events53. In this stage of disease evolution, the anesthetic risk for this patients is high, being necessary a strictly perioperative management in order to prevent further complications.[54]

Anti-phospholipidic syndrome (APS) is a disorder associated with recurrent arterial or venous thrombotic events and pregnancy morbidity, along with the presence of antiphospholipid antibodies (anticardiolipin antibodies and/or lupus anticoagulant) [55]. Renal disease in APS is characterized by interstitial tubular or glomerular injury due to obstruction of the vessels. Renal manifestations include thrombotic microangiopathy, renal vein thrombosis, renal infarction, renal artery stenosis or malignant arterial hypertension.[56] APS nephropathy was found to be statistically correlated with arterial thrombosis, fetal loss, and the presence of lupus anticoagulant. These characteristics seem to be linked to an increased prevalence of hypertension, raised serum creatinine, and interstitial renal fibrosis.[57]

The therapy of renal disease in SLE is a challenge for the practitioner. An early and targeted intervention can influence the disease' course. The mortality of SLE decreased considerably after the introduction of cyclophosphamide as the major weapon against lupus nephritis, the renal disease no longer impairing the survival rates of these patients. The results of a recent study sustain the role of combined therapy with intravenous pulses of cyclophosphamide and methylprednisolone in the improvement of lupus nephritis [58,59]. However, the long-term use of cyclophosphamide can cause major side effects, such as bone marrow suppression, hemorrhagic cystitis [60-63], gonadal toxicity and, eventually, the development of neoplastic disorders or can complicate some surgical procedures [64-66], with subsequent infections.[67-70] On the other hand, studies have very good results on long-term remission rates and the ability to achieve a second remission with currently recommended intravenous cyclophosphamide regimens. Concerning the new therapeutic options [71,72], it seems that biological agents, such as blockers of other co-stimulatory pathways (for example, CTLA4-Ig), monoclonal antibody against CD20, anticomplement (anti-C5b) and anti-cytokine treatment, induction of T and B cell tolerance, and hormonotherapy, could be involved in the management of lupus nephritis, but these therapies still have no sustainable evidence.[73-75]

CONCLUSIONS

SLE is an autoimmune disease in which self-tolerance is lost, with polymorphic manifestations that represent a real challenge, both for diagnosis and for treatment. SLE often involves severe complication in the various systems of the body, causing a decrease in the patient's quality of life. Renal impairment is one of the most serious complications and could lead to end-stage renal failure. Lately, the focus is on early diagnosis and targeted-treatment for the good management of these patients.

Concepts for the implementation of a technological platform for the production of specific antidotes for CBRN medical protection

Viorel Ordeanu[1,2], Diana M. Popescu[1], Marius Necsulescu[1], Lucia E. Ionescu[1], Adrian C. Popa[1], Roxana C. Sandulovici[2]

Abstract: *All large armies (EU and/or NATO) have pharmaceutical production facilities to provide the necessary antidotes for the troops and the population: The French Army Medical Directorate produces many military-specific pharmaceutical products in its own laboratory, the Turkish Army owns its own medicines factory, including CBRN antidotes, the US Army, in addition to a sustained drug purchase program in the pharmaceutical industry has launched a new concept: Pharmacy on demand.*

Providing the armed forces with antidotes is a necessity, the concept for their endowement in this sense can be based on imports (sometimes impossible to achieve) or on the national development of a specialized production structure.

The design or construction of a specific production capacity for antidotes can be accomplished on multiple variants, with a complexity proportional to the identified need. The total costs are high, but the objective and implementation of effective antidote supply mechanisms is a security guarantee for the armed forces and the civilian population (through commercialization to allied forces), given the risks of terrorist threats and hybrid warfare.

Keywords: *medical protection, antidote, production, technological platform, medical countermeasures, pharmaceutical technique, orphan drug production*

INTRODUCTION

The creation of a technological platform for the production of antidotes for CBRN medical protection is presented in synthesis, as an initial medical approach to a complex problem of the pharmaceutical industry, resulting from a practical need for therapeutic countermeasures in the field of CBRN protection and a strengthening the capacity of action.

The strategic need to create a technological platform for the production of specific antidotes for CBRN medical protection has led to the concept of a technological platform for the production of specific antidotes, on technical, constructive and product volume variants, depending on needs and possibilities [1].

1. Existing solutions in other countries

Worldwide, large armies (EU and/or NATO) have pharmaceutical production facilities: The French Army Medical Directorate produces many military-specific pharmaceutical products in its own laboratory. The Turkish Army owns its own medicines factory, including CBRN antidotes, the US Army, has a sustained antidotes purchase

[2] “Titu Maiorescu” University, Bucharest, Romania

program in the national pharmaceutical industry [2].

The US has begun research for a new concept: Pharmacy on demand. Recent advances within the Defense Advanced Research Projects Agency (DARPA) show that it is possible to achieve complete, miniaturized and flexible platforms for the manufacture of pharmaceuticals. Current progress related to continuous flow synthesis, chemistry, biological engineering coupled with online analysis, automation and improvement of control measures may be elements that enhance the pharmaceutical supply chain and drug production. These new technologies, together with scientific advances, can be the prerequisites for authorizing the "on demand" manufacture of drugs on the battlefield and in other austere environments, increasing the readiness for CBRN threats, increasing the ability of medical authorities to respond to natural disasters and other catastrophic events, minimizing drug shortages, addressing gaps in the orphan drug market, supporting ongoing efforts towards personalized medicine, and improving access to needed medication in disadvantaged areas around the world. The modular platforms being developed through DARPA programs can in the future improve the safety, efficiency and timeliness of drug manufacturing [3].

2. General considerations regarding constructive variants of technological platforms for the production of antidotes for CBRN medical protection

In order to create an image regarding the international context, the Military-Medical Research Center through the Army Information General Directorate has obtained information on the antidote portfolio and how to provide them to different NATO armies [4].

The concept of providing specific antidotes for the protection of the armede forces and the population must meet the Security needs of Romania, and must take into account complex economic, social and legislative realities. Although many states have their own production facilities, they do not provide their own antidote portfolio, being approved for use in that state, based on special legislative regulations. If there are entities willing to sell antidote products (excluding the top ones), over time the company may modify the sales policy or may go bankrupt, the Romanian state remaining out in the open in regars to their provision.

Some CBRN Antidotes have a special regime of use, being necessary to be used in a very short time from the action of the causative agent, having to be in stock and distributed to the armed forces. Also, the preventive antidotes for counteracting the effects in the event of exposure must be in stock in sufficient quantities. It is therefore necessary to modify the regulations regarding the establishment and maintenance of the stocks of these products, assuming from the beginning a periodic, bearable financial loss, in exchange for obtaining the medical security of the troops and maintaining the action capacity.

In the same way that the Air Force provides Security and not revenues, the costs for the endowement with technological means, personnel training and operation of the technological means being important, with much lower costs the security of the personnel can be ensured by creating a specialized structure in the production of antidotes.

The concept of developing the Technological Platform for the production of antidotes for CBRN medical protection is presented in synthesis, as an initial medical approach to a complex problem of the pharmaceutical industry, resulting from a practical need for CBRN medical countermeasures in the field of CBRN protection. It should be noted that worldwide, the pharmaceutical industry, which is one of the most profitable in the world, was removed from the Health field and was included in the Industry field. This denotes the fact that the economic-financial function (the profit of the investors) prevails the social function, which ended up being considered secondary. Large producers bypass antidotes as orphan drugs, having a small retail market, due to the fact that the profits would not cover the investment. Thus, antidotes are difficult or impossible to obtain in crisis situations. Therefore, it is up to the State to guarantee the operability of the armed forces under the conditions of CBRN events, even with slight financial losses [5, 6, 7].

Depending on the need established by the competent bodies, several variants of CBRN antidote production facilities can be designed. These variants must have flexibility, depending on the situation, and their production will adapt immediately to the estimated volume for the given context. Whatever the risk, direct or indirect consequences with CBRN classification will be projected on the population requiring the adoption of specific and appropriate medical countermeasures, cascading with the management of epidemics or epizootics. It shall suffice to recall the aftermath of the earthquake in Haiti that led to the worst epidemic of cholera in recent history, as well as the civil war in Yemen that caused a catastrophic cholera epidemic. In both situations, multiple systems were affected that facilitated the outbreak of epidemics, the national health services were not properly prepared, and the international aid appeared late and in a volume that failed to cover the necessary.

Depending on the identified needs and the allocation of funds by the competent bodies, the solutions for the manufacture of specific CBRN and related antidotes extend over a wide spectrum. In the following are provided three variants: minimum level (galenic laboratories for antidote production), medium level (pharmaceutical laboratory for antidote production) or maximum level (drug factory or specialized department for antidote production).

The ideal solution is a new drug factory that complies with European Union GMP and GLP regulations. In principle, the Integrated Technology Platform for the production of specific antidotes for CBRN medical protection should include:

- Pharmaceutical laboratories for the production of antidotes, by categories;

- Laboratory for pharmaceutical control and quality assurance;

- Production laboratory for chemical synthesis of pharmaceutical substances;

- Microbiology laboratory for in vitro analyzes and tests of pharmaceutical microbiology, required by the regulations in force, such as the Romanian Pharmacopoeia X and the European Pharmacopoeia 10/2016 [8, 9].

- Biobase for in vivo analyzes and tests on experimental animals, required by the regulations in force, according to the Biosafety Guide for medical laboratories, MS 2006;

- Research and development laboratories for applying own research in pharmacology and/or pharmacy;

- Annex facilities and utilities.

The costs with the initial investment and the exploitation for such a production facility of the antidotes (orphan drugs) cannot be covered by sales, which is an impediment in making a political decision to implement such a solution. Given the major risk for public health in crisis situations and the possible catastrophic implications at national and international level, it is necessary to establish directions of action, depending on needs and possibilities, on variants. This pharmaceutical industry facility must be subordinated to a governmental structure for rapid coordination between central structures in order to limit the effects of the crisis situation.

The technological platform for the production of antidotes for CBRN medical protection, depending on needs and possibilities, can be developed in three variants: minimum, average or maximum.

For the medical protection against CBRN agents, the minimum necessary antidotes for the peacekeeping units belonging to the Ministry of National Defence, for the Ministry of Internal Affairs and for the secret services involved in response and the specific risk groups (personalities, medical service, etc.) must be calculated on the basis of a political-military decision, which we estimate at over 100,000 individual doses for each assortment.

3. Minimal variant: adaptation of existing spaces

If the risk and threat become imminent and there is not yet a facility in the country to produce CBRN antidotes, it would be possible based on a government approval with the partial suspension of the provisions of the Medicines Law, to prepare by micro-production (daily galenic lots) the antidotes necessary, for the possible emergency use of exposed, contaminated or ill personnel, as a result of the effect of CBRN attacks. Moreover, at the end of the Medicines Law there is a paragraph that provides this exception for crisis situations [10], respecting the basic rules for the operation of a pharmacy with its own laboratory (galenic), under the coordination of the College of Pharmacists of Romania and with the approval of the Pharmaceutical Inspection. The antidotes produced in such manner, would be from the spectrum of medical prototypes against chemical warfare agents (CWA): neuroparalytics, vesicants, asphyxiants, etc., against radiological warfare agents (RWA): radioactive isotopes and irradiation, as well as biological warfare agents (BWA): living biological agents, toxins [11]. In the event of force majeur, the necessary specialized personnel can be provided from the competent personnel belonging to the military scientific research structures, seconded for technical assistance to the facility that ensures the first phase microproduction. The benefits are represented by the minimization of costs and the deficiencies are represented by latency with which the affected personnel gets the antidotes, sometimes with disastrous effects and the creation of stocks of raw materials.

4. Medium variant: modernization of existing spaces

Since 2002, in the context in which Romania was to become a member of NATO and the EU, the idea of creating an infrastructure for the production of antidotes had been proposed, by modernizing some areas in the heritage of the Ministry of National Defence.

Thus, with the support of a specialized company from Austria, the necessity of using an industrial type construction or pavilions on reconfigurable reinforced concrete structure was proposed.

In the case of pavilions, on the ground floor could be arranged the department of self-injecting syringes for antidotes (manufacture, filling and storage), with the creation of clean room areas for an automatic line of Austrian origin. Upstairs could be created a department of solutions and powders as well as pharmaceutical control laboratories. Also, related spaces of the building (eg attic / bridge) could be adapted for storing raw materials, finished products or laboratory technique. The connections between the departments and the storage spaces, in order to comply with all the necessary flows, would be made wherever necessary and from light constructions outside the existing spaces.

The estimation made by the Austrian specialists for the plant for the manufacture of self-injecting syringes exceeded the value of 10 million euros, and for the whole "turnkey" project, with spaces, equipment, consumables, commissioning and training of the personnel amounted to about 19 million euros. It was suggested to include a financial reserve of 1 million euros for operation (raw materials, utilities, etc.) the general total amounting to 20 million euros. At the level of that period the investment seemed very high, but it was considered to be bearable by equipping the army with the avoidance of imports, ensuring the necessary for the protection of the population and recovering a part of the investment by the possibility that the surplus of products could be exported to the allied armies, following that Romania would become a supplier of antidotes (manufactured according to European Union standards) for the eastern flank of the alliance. The investment was likely to become profitable for the country.

Another explored work option was the creation of a facility in collaboration with the Turkish army's medicines factory, which would have turned out much cheaper, but which did not have approvals in line with European norms. This meant that after the accession to the EU the antidotes would no longer be used in Romania and, therefore, they could not have been exported to other EU countries. This option was eventually discarded.

The average variant could cover the need for specific antidotes for medical countermeasures against CBRN weapons/agents for the general mobilization military personnel (the Ministry of National Defence, The Ministry of Internal Affairs, the Secret Services), including for the risk groups and for the vulnerable population, with the capacity to produce over 1 million doses from each assortment.

5. The maximum variant: de novo construction of specific facilities

The facilities for the production of CBRN antidotes must comply with the CBRN protection requirements, as the manufacturing conditions for the drugs are more severe, according to the Medicines Law and must comply with the European norms in force.

Under these conditions, the old variants are no longer sufficient, except as a breakthrough formula in case of force majeure and therefore an approval for the establishment of a new building shall be needed, whose design, construction and equipment must comply with the minimum requirements for the pharmaceutical industry. According to the Medicines Law, it would result in a medicines factory, which should include: adequate space, unique flows, equipment, specialized personnel and procedures, according to the current requirements in the field.

This facility may be the only one able to ensure the complete protection of Romanian troops and of the civilian population, including of the military forces on the national territory and, in addition, an eventual export within the NATO or EU alliance. Depending on the political-military decision, this production could reach over 20 million doses from each assortment.

The space should in principle be presented as a miniature medicines factory or at least as a pharmaceutical manufacturing laboratory, in accordance with the WHO GMP and GLP standards [12, 13, 14]. The construction should be based on the concept of clean rooms in a separate or independent pavilion, resistant to an earthquake of 8 degrees on the Richter scale, with walls, ceiling and floor watertight and washable, with a height of approximately 5 m (for false ceiling and high floor for masking the pipes system), watertight doors and windows, divided into spaces for the main activities. The result is a total of at least 500 square meters, of which a minimum of 400 square meters inside the pavilion and a minimum of 100 square meters outside for the assembly of the technical installations. The clean rooms must comply with the provisions of the Good Laboratory Practice (GLP) and Good Manufacturing Practice (GMP) guidelines, which are updated by the National Agency for Medicines and Medical Devices, depending on the biosafety level of the area: clean, aseptic, sterile.

The division of space and the access ways must allow the creation and the compliance of unique flows for the: personnel, equipment, materials and raw materials, for semi-finished products and finished products, solid and liquid waste, air (with a cascade of negative or positive pressure gradients, as applicable). This aspect is essential for the protection of the product and the operator. If they are to be protected from natural or intentional contamination of the environment, the enclosure will have positive pressure on the outside. If on the premises they are working with hazardous materials (biological, chemical, radioactive, etc.), a negative pressure must be maintained on a permanent basis, in order to avoid leaks that contaminate the outside. This is also one of the operating principles of highly secured laboratories (P4 or BSL4) [15].

The pavilion must have permanently complex systems of protection and alarm for the perimeter, for the building and for the workrooms. The construction and equipment works can only be performed by specialized and authorized companies in the field, that have the necessary experience, because the new objective must obtain manufacturing authorization for medicines, including injectables.

The endowment consists mainly of the purchase of a new plant for the manufacture and the filling of self-injecting syringes (about 10 million euros) and equipment for conditioning and filling the vials with powders, tablets, solutions, ointments, etc., of pharmaceutical control, packaging and of the mentioned technical installations, of the current pharmaceutical equipments: apparatus, inventory objects, consumables, protective equipment, raw materials, packaging, furniture, office supplies etc. (approx. 10 million euros) which are added to the construction costs, estimated at 23 million euros, of authorization, accreditation and training. Therefore, we are speaking of a total investment of about 50 million euros.

The necessary specialized personnel shall consist of a minimum of 23 specialists.

The procedures must describe each operation and must comply with the recommendations of the European Union’s Good Manufacturing Practices (GMP), Good Laboratory Practice (GLP), Good Clinical Practice (GCP) and must be endorsed by the National Agency for Medicines and Medical Devices of Romania (NADMR).

OBSERVATION

The need and the opportunity to design, build and operate this specific objective of pharmaceutical production is based on the realization of a prefeasibility study, which must be done with the multidisciplinary consultation of the specialists from qualified institutions, future operators and/or beneficiaries of this investment.

The need is conditioned by:

- The spectrum of threats in the current international political-military context, doubled by the threat of international terrorism, including with ADM CBRN;

- In order to ensure survival in CBRN events, endowment with antidotes is mandatory, in medical practice and especially in military medicine;

- In some crisis situations, the provision of antidotes may be deficient due to the lack of sufficient quantities and the impossibility of provision from import

- The first necessity is represented by the endowment with self-injection syringes of the active military staff, followed by the de-commisioned staff and the risk population, according to NATO norms.

Implementation costs: the total costs are important, but the objective can be amortized in a short time and the social benefit is very high; the average variant (proposed by the Austrian specialists) is estimated at 20 million euros; the optimal variant (the antidote medicines factory, in accordance with WHO, GMP norms) exceeds 50 million Euro, and the minimum variant (the adaptation of the existing one in case of force majeure) without self-injection syringes, under 1 million euro. Operating costs: depending on the variant and the production requirement, up to 1 million euros/year.

Conditions and legislation for certification/accreditation/ operation: Medicines Law, GLP, GMP, ISO 9001 norms.

It is possible to organize, within the military-medical system or in cooperation with the civilian system, a virtual structure for the production of specific CBRN antidotes, preventive and curative, and specific procedures that, in case of force majeure, can start producing small quantities of antidotes simple, necessary to the affected people.

Military history shows that, unfortunately, most of the time it is preferred to invest in offensive equipment and means at the expense of the defensive ones, ignoring the importance of protecting the troops and the civilian population. The human being is the most precious asset, both socially and militarily, since modern warfare uses sophisticated equipment whose use is only operated by highly qualified personnel, sometimes impossible to replace. Neglecting the protection of human capital can constitute the "Achilles heel" within a strategy of defense or army endowment, complex problems of the pharmaceutical industry, resulting from a practical need for CBRN medical countermeasures in the field of CBRN protection. This vulnerability is common to all armies, from all times.

CONCLUSIONS

The article presents brief elements regarding the development of a production/ microproduction facility of antidotes for CBRN medical protection, as an initial medical approach to a complex problem of the pharmaceutical industry, resulting from a practical need for CBRN medical countermeasures in the field of CBRN protection.

The problem is extremely complex, for choosing the optimum solution being involved many aspects (the doctrine on defense, the need for the military and population) established by the decision-makers taking into account the short and medium term threats to the security of Romania, the provision of funds and human capital etc.

It is possible to set up or build a specific production/ microproduction capacity for antidotes, depending on the complexity. The total costs may be high, but given the risk of terrorist actions of hybrid warfare in our geographical area, the military benefit of strengthening the capacity for action and the social one are very high.

The purpose of this article is to bring into discussion elements on issues of medical-military interest that can generate a constructive exchange of ideas between the decision makers that can lead to the identification of an optimal solution.

Content, hierarchy, intensity of motives and their possibility to be implemented in servicemen with various levels of effectiveness of service activity

Oleksandr Kolesnichenko[1], Yanina Matsegora[2], Ihor Prykhodko[2], Stanislav Larionov[3], Anastasiia Bolshakov[4], Olena Bilyk[5], Svitlana Izbash[3], Viktoriia Kuzina[6], Vitalii Panok[7], Vira Kramchenkova[8]

Abstract: *In accordance with the results of conducted research there were figured out the content, hierarchy, intensity of motives and their possibility to be implemented in servicemen with various levels of effectiveness of service activity. 2435 male servicemen participated in the research, they equally presented all the operational and territorial military unifications and units of the National Guard of Ukraine. Each unit proportionately presented officers as well as military personnel under contract who included the participants of hostilities and those who did not have such experience. Examination of various aspects of servicemen motivation was conducted with the help of the following the methods which were standardized being based on the Ukrainian selection "Close Questionnaire of Examining the Motivation of Professional Choice Made by Applicants of the Ministry of Internal Affairs", "Questionnaire of Estimation of the Effectiveness of Military Tasks' Execution by Servicemen of the National Guard of Ukraine", questionnaire on "Sense-Bearing and Life Orientations", the methods of "Studying the Motivational Profile of Personality", and "Locus of Control". There was conducted the cluster analysis which gave the possibility to figure out six motivational types connected with the effectiveness of servicemen operational activity. Motivational types were located between the poles which were introduced by two dimensions: self-efficacy (autonomous and controlled motivation) and motivation of helping others (motivations of public service - selfishness). Those motivational types of servicemen were the following: motivated by public service, stagnant, prosocial, romantic, deficient, and dependent. Distinguished types included the content, hierarchy, intensity of motives and their possibility to be implemented.*

Keywords: *motive, motivational sphere, effectiveness of service, servicemen, public service*

INTRODUCTION

Motivation as a factor of professional as well as personal development was significant but was not completely discussed aspect of a complicated issue of professiographical examination of servicemen operational activity; though, thenecessity of examining the proposed topic was mostly caused by a need of practice (Prykhodko I., Matsehora J., Lipatov I., Tovma I., Kostikova I., 2019). Experience of using military units and formations of the Armed Forces of Ukraine (AFU) and of the National Guard of Ukraine (NGU) during combat operations in Ukraine since 2014 strongly convinced that with a considerable degree successful conduction of combat and operational tasks depended on the level of personnel's motivation. Its independent level during operations devaluated any advantages of military formations in logistics and professional development; moreover, it provoked combat stress (Prykhodko I., 2018). Before the combat conflict on the East of Ukraine daily service of servicemen faced difficult times including low level of logistics and salary, absence of prospects to receive their private accommodation, and plenty of other social and

domestic problems which brought the situation to the line where servicemen made inappropriate choice (Prykhodko et alia, 2019). Insufficient level of motivation occurred in negative facts of refusal of some parts of the Ukrainian military formations' personnel to continue the service on the territory of the Autonomous Republic of Crimea, of Donetsk and Luhansk regions at the beginning of 2014 as well as in adequate efficiency of units' operation which were manned by mobilized servicemen, in significant quantity of suicides, crimes, and violations of military discipline among servicemen at the Anti-Terrorist Operation zone (further Joint Forces Operations) (Prykhodko et alia, 2019).

Besides the fact that there were many scientific researches of peculiarities of personal motivation concerning professional activity under extreme conditions, namely: combat operations constantly made adjustments to components of its diagnostics and formation. Especially that issue was related to the sphere of professional activity of the Ukrainian servicemen. Military service included participation in combat operations, execution of operational tasks connected with vital risks, combat trainings, and daily activities (Kolesnichenko, 2018). Motivation concerning the military activity included a range of various social and psychological conditions, and determined the complex of positive as well as negative aspects of military service (Kapliuchenko, Prykhodko, 2019). Motivation included the reveal and actualization of inner resources of servicemen and creation of positive motivation in combination with external conditions (Prykhodko et alia, 2019). Its specifics depended on personal peculiarities as well as on professional activity.

The vast majority of modern foreign researches on individual motivation concerning professional activity, namely, under extreme conditions, was focused on the paradigm of the theory of self-determination. In 1985 this paradigm was proposed by Deci and Ryan (1985) after that it was accepted as a reliable empiric theory. According to its core postulates human motivation was divided into external and internal, internal included three congenital universal psychological needs: competency (need of people to show their abilities), autonomy (right of choice to choose the profession), and interrelationship (need of feeling their own involvement into social groups and/or spheres of activity). This theory led to the conclusion that different regulating processes which, being the core of achieving goals, were correlated with the effective functioning and welfare. Different contents of goals were correlated with the quality of behaviour, mental health, and with the level of needs' satisfactionin different ways.

To prove the key notions of the theory of self-determination Gillet, Becker, Lafrenière, Huart, and Fouquereau (2017) analyzed interrelationship between motivating profiles of servicemen and civil workers. The results of their research showed that profiles were differently connected with accepted organizational support as well as with involvement into the activity of both selections includingcommunication and support from the side of management and with positive and negative effects in the second selection. Moreover, servicemen with the highest indicators of autonomous motivation presented the highest levels of organizational support acceptanceand involvement into activity. Nevertheless, the highestlevel of autonomous motivation was connected with the highest level of communication, support of commander, and positive influence.

Using the theory of self-determination as a theoretical basis, Chambel, Castanheira, Oliveira-Cruz, and Lopes (2015) created a model that included the servicemen's perception of organizational support on exchange between commanders and members of military staff, professional motivation and welfare. The results showed that motivation concerning autonomous activity was significantly connected with both contextual factors. Besides that, motivation concerning autonomous work was positively connected with its involvement into activity and was negatively connected with professional burnout while controlled motivation demonstrated the opposite reaction.

Foreign researchers (Griffith, 2008; Helmus et alia, 2018) to prove main aspects of the theory of self-determination distinguished institutional and pragmatic motivation as well as their combination. Internal motivation was included into the process of launching the activity because that was interesting and could self-satisfy despite the activities turned to the achievement of external goal. Though, Graffith (2008) using the analysis of motivation of the US National Guard servicemen included into the list of institutional type such internal motives as: patriotism, desire to test themselves, desire to be useful for country and society. Pragmatic motivation to serve was demonstrated through general attitude to army as if it was an employer who made delightful proposition.

In another research Helmus et alia (2018) from RAND center distinguished key motives of entering the US Army and revealed the specificity of army life reality. The results showed that the choice of future servicemen selection in the USA was influenced by two groups of motives which were interrelated with each other: institutional and pragmatic. The key motives to choose the profession of the US Army serviceman were "adventures and travelling", "advantages", "stability of the work and salary", "avoidance of negative surrounding", and "professional education".

Moreover, Helmus et alia (2018) figured out that on the contrary those servicemen who were motivated by pragmatic incentives tended to long-term military service in contrast with those who chose the service as a “call of their heart” being based on institutional motives. Thus, the most of candidates chose the military service in the US Army due to pragmatic (material) reasons, but for the majority of recruits the military service became the work and only after that – call of their hearts.

The research of Bury (2017) which was based onthe determination of motives of recruiting and retention in logistics’ divisions of the British Army reserve demonstrated that servicemen who served because of institutional motives were focused on longer service. Servicemen with pragmatic motivation were less satisfied with the conditions of their service and entered the military sphere to follow the contract only.

Woodruff (2017) had the same conclusion which pointed out that internal motives created stronger connections with army and military valuesthan external motives such as: salary, experience for future professional activity, finances for future education, etc.

The Norwegian experts Johansen, Laberg, and Martinussen (2014) proved that institutional and pragmatic motives could cohabit and a serviceman who was interested in salary, help and economic welfare was not obligatory a bad soldier. The authors pointed out that during the international mission beyond the borders of their own country it was hard to maintain the ideal images of military service; however, mainly the loyalty to traditional military ideals were the best motives of serving and factors of effective military organization.

Grigorov and Spirdonov (2018) confirmed the theses that there was institutional and pragmatic motivation. They conducted the research to distinguish core motives of choosing the military profession in the Republic of Bulgaria and suggested that the dominant motivational structures in the process of choosing the profession was the coexistence of leading factors which were connected with pragmatic motivation in comparison with internal factors which related to one definite work, independence, achievement, and recognition.

According to Taiyang (2010) the system of motivation to serve in the Chinese Army was determined with the factors of tradition and culture: national flag as a symbol of honour, courage, role of model caused the involvement into nobility and caring about other people; non-material motivated stimulation.

Analyzing the motivation of the Brazilian servicemen, Rodrigues-Goulart (2006) highlighted that it always had crucial importance for servicemen who executed tasks under combat (extremal) conditions which posed risks for their life and health. According to the researcherfor many situations motivation was a core to succeed in battle. Rodrigues-Goulart distinguished the following motives of military profession: sense of obligation, belonging to military sphere, responsibility, sacrificing, need of fate, desire of adventures, leadership, working abilities, tendency to recognition and awards, ideas of legitimacy of war, hope and victory, hatred of enemies, and need of self-preservation.

In accordance with Catignani (2004) “strong spirit” of military division was equal to high combat motivation. It was impossible to overestimate the importance of combat motivation to succeed in execution of military operations such as patrolling as well as full-scale war. Combat motivation was key factor that gave possibility to ordinary army to succeed in conflicts; talking about Israel it was called “secret weapon” of the army. Catignani (2004) pointed out that there was “a tough connection between cohesion, motivational level of servicemen and combat effectiveness”.

Analysis of modern scientific works indicated unbelievable urgency of the problem of servicemen motivation to act under extreme conditions in different countries all around the world. Systematization of analyzing the peculiarities of professional motivation of servicemen gave the possibility to conclude that motivation was one of the most significant factors for military division to achieve the posed goals in many situations which occurred in the process of executing combat operations under extreme conditions.

The aim of the research was to determine the content, hierarchy, intensity of motives and their possibility to implement them in servicemen with various levels of effectiveness of service activity.

MATERIALS AND METHODS

Respondents

The research was conducted from 2019 to 2021. There participated 2435 servicemen of the NGU who equally presented all the operational and territorial divisions and military units of the NGU. Each unit equally presented their officers – 29.84% (from Second Lieutenant to Colonel) and servicemen under contract – 70.16% (from Crewman to Warrant Officer), participants of hostilities and those who did not have such experience. The age of the respondents was from 20 to 55. All procedures carried out in the study conformed to the ethical standards of the 1964 Helsinki Declaration and its later amendments. All participants gave consent for their data to be used in this research.

Instruments

To determine various aspects of servicemen motivation there were used the methods which were standardized being based on the Ukrainian selection.

1. “Close Questionnaire of Examining the Motivation of Professional Choice Made by Applicants of the Ministry of Internal Affairs” by Moskalienko (2002). This questionnaire was developed by the Ukrainian researcher for professional psychological selection for future policemen education, it gave possibility to evaluate: “Motives Related to Objective Socially Posed Tasks and to Content of Profession”, “Motives Related to Personal and Professional Development”, “Independent Profession Selection”, “Dependent Profession Selection”, “Motives Related to External Prestigious Professions and Financial Welfare”, “Motives Related to Romanticization of Profession”, “Motives Related to Eagerness of Compensation of Temper Flaws”, “Antisocial Motives (attitude to profession was as if it was a way to satisfy own antisocial needs)”. The instruction of this method proposed to answer the question concerning the reason of choosing this profession where the respondents using a scale made of 5 points could estimate 40 statements which described the profession of law enforcements.

2. “Methods of Studying the Motivational Profile of Personality”by Ritchie and Martin (1999). The use of this method gave the possibility to determine the urgent motivation of professional activity. It had the following scales: “Need of High Salary and Financial Benefits”, “Need of High Working Conditions and Comfortable Surrounding”, “Need of Accurate Structurization of Work and Feedback”, “Need of Social Relations”, “Need of Forming and Supporting Long-Term Stable Relations”, “Need of Obtaining the Recognition by Other People”, “Need of Posing Brave and Tough Goals and of Achieving Them”, “Need of Interesting and Socially Beneficial Work”, “Need of Self-Improvement and Development as Personality”, “Need of Being Creative, Thoughtful, and Open for further Ideas Employee”, “Need of Diversity, Breaks and Stimulations, Eagerness to Avoid Everyday Routine”, “Need of Manipulation and Power, Eagerness to Control the Other People”. This questionnaire included 33 questions with 4 variants of answers where the respondents had to replace 11 points in accordance with the importance of the answers.

3. Method of “Will-Regulated Personality” by Hutkin and Mikhalchenko (2000) gave the possibility to determine general indicator which characterized willed organization and willed peculiarities of personality: organization of will and sense, organization of activity, determination, perseverance, self-control, and self-reliance. This method included 56 questions with 4 variants of answers.

4. Method of “Locus of Control” in modification proposed by Ksienofontova (1999) which gave the possibility to analyze internal orientation of serviceman personality, his/her ability to recognize and take responsibility for his/her decisions and actions. This method included 40 statements which respondent could agree or disagree with. This questionnaire determined 17 options of internality: general internality, internality in thoughts about life in general, internality in description of personal experience, internality in the sphere of achievements, internality in the sphere of fails, tendency to self-incrimination, internality in the sphere of professional activity, professional and social aspect of internality, professional and processual aspects of internality, internality in interpersonal communication, competence in the sphere of interpersonal relations, responsibility in the sphere of interpersonal relations, internality in the sphere of family relations, internality in the sphere of health, negation of activity, readiness for activities which was connected with difficulties overcoming, readiness for self-planning, acting and responsibility for their activities.

5. Test of “Sense-Bearing and Life Orientations”in adaptation made by Muzdybaieva (1998). This test was the adapted version of test “Goal of Life” by Crumbaugh, Maholick (1988). Within the further work with the method there was developed a scale of searching for sense-bearing and life goals (Crumbaugh and Maholick, 1969). It was planned as an additional scale for the test devoted to life understanding. According to the ideas of the authors the scale had to measure the strength of motivational tendency to search for sense of life; thus, it was opposite to the scale “Goal of Life” – the more goals of life there were the less need for their search.

Adaptation of this text into the Russian language was completed by Muzdybaiev (1998). The factor structure of the Russian version of the text was determined during special research. This research demonstrated that despite the small quantity (20 points) during the factor analysis there were distinguished six factors on thebasis of which there were marked out some subscales in the final variant of sense-bearing and life orientations.

6. “Questionnaire of Estimation of the Effectiveness of Military Tasks’ Execution by Servicemen of the National Guard of Ukraine” by Prykhodko (2013) gave the possibility to estimate the level of development of important professional qualities and peculiarities of executing the servicemen’s combat operations. Experts were the commanders of servicemen who participated in the

research.

The questionnaire included 37 criteria of estimation. In the process of estimation experts used the scale with 5 points: 5 points was the maximal possible level of development of estimated professional important quality or maximal level of effectiveness of the estimated aspect of service. 0 points was used to determine the absence, undevelopment of estimated important professional quality or full inefficiency of subordinate individual in estimated aspect of combat operations. Informative paragraphs of this questionnaire revealed all the processual aspects of work, peculiarities of professional communication and motives, professional skills, and possibilities of productive work.

Mentioned methods were standardized for the Ukrainian selections, they were often used to determine the peculiarities of professional motivation of servicemen and law enforcements of Ukraine.

Data Analysis

A cluster analysis was used to compare the data of psychodiagnostics scales in the study groups. To present the data, we used the main descriptive statistics (arithmetic mean M and standard deviation SD). To reliably detect significant differences between comparative groups, the t-Student criterion was used (significance level p<.1, p<.05, p<.01). Mathematical data were processed through SPSS 17.0

RESULTS

Conducted cluster analysis gave possibility to distinguish 6 groups which differeddue to their ways of estimation of combat operations effectiveness as well as typical sphere of motivation and will. The indicators for psychodiagnostic methods that determine the characteristics of the identified types of motivation in servicemen are showed in Table 1.

Table 1: Indicators for psychodiagnostic methods that determine the characteristics of the identified types of motivation in servicemen (in standard points)

Psychodiagnostic methods	MWE	MHE	HE	WE	MLE2	MLE1
“Questionnaire of Estimation of the Effectiveness of Military Tasks’ Execution by Servicemen of the National Guard of Ukraine”						
General indicator of the effectiveness of service and combat activities	19.43±3.22	20.43±2.16	21.05±2.59	18.52±1.93	20.23±1.88	20.40±1.71

General indicator characterizing the volitional organization of the personality	87.78±12.20	84.21±12.48	104.04±10.10	77.62±18.06	63.78±5.33	109.81±7.75

Notes: MWE – middle level of effectiveness with tendency to weak indicator of effectiveness; MHE – middle level of effectiveness with tendency to high indicator of effectiveness; HE – highly effective; WE – weakly effective; MLE2 – middle level of effectiveness; MLE1 – middle level of effectiveness

Table 2 show the significance of differences between the proposed types according to the scales of methods for describing the features of the motivation of military personnel.

The group of highly effective (HE) servicemen included 35% of the general selection of the research. This group consisted of 1/3 from every category which participated in the research: officers, military personnel under contract, and participants of hostilities (PH).

The group of weakly effective (WE) servicemen included 4% of the general selection of the research. This group consisted of 85% of military personnel under contract and 15% of officers. 85% of this group were the participants of hostilities.

There were two groups with middle level of effectiveness of operational activity. Group number 1 with middle level of effectiveness (MLE1) was more numerical – 15% of the general selection of the research. This group consisted of 2/3 of military personnel under contract and 1/3 of officers. The status of the participants of hostilities belonged to 3/4 of respondents.

Group number 2 with middle level of effectiveness (MLE2) was less numerical – 7% of the general selection of the research. The indicator of combat operations’ effectiveness was distinguished as 20.23±1.88. This group consisted of 87% of military personnel under contract and 13% of officers. The status of the participants of hostilities belonged to 48% of respondents.

There was distinguished one more group which took intermediate place between the groups with high effectiveness and with middle level of effectiveness. It was marked as a group with middle level of effectiveness with tendency to high indicator of effectiveness (MHE). The group included 15% of the general selection of the research. This group consisted of 70% of military personnel under contract and 30% of officers. The status of the participants of hostilities belonged to 50% of respondents.

Moreover, there was detected the group which indicator of combat operations’ effectiveness took intermediate place between the group with middle level of effectiveness and the group with weaklevel of effectiveness. It was marked as a group with middle level of effectiveness with tendency to weak indicator of effectiveness (MWE). The group include done-in-four participant of the research. This group consisted of 73% of military personnel under contract and 27% of officers. The status of the participants of hostilities belonged to 45% of respondents.

According to “Close Questionnaire of Examining the Motivation of Professional Choice Made by Applicants of the Ministry of Internal Affairs” (Moskalienko, 2002) there were highlightedthe motives of choosing military profession by group HE, but their indicators were significantly weaker than those of groups WE and MLE1.

The peculiarity of motives of choosing military profession in this group was determined by hierarchy indicators.

Thus, the most expressed were “Motives Related to Objective Socially Posed Tasks and to Content of Profession”.

Table 2: The significance of the differences between the proposed types according to the scales of methods for describing the features of the motivation of military personnel (in standard points)

The next stage of hierarchy was occupied by “Independent Profession Selection”, “Motives Related to Personal and Professional Development”, “Motives Related to Eagerness of Compensation of Temper Flaws”, “Motives Related to External Prestigious Professions and Financial Welfare”. Law there were “Motives Related to Romanticization of Profession”. The lowest stage of hierarchy was occupied by “Dependent Profession Selection” and “Antisocial Motives”. The indicators of “Dependent Profession Selection” and “Antisocial Motives” were the lowest among the compared groups (they were the lowest only in participants of group MHE).

According to “Methods of Studying the Motivational Profile of Personality” (Ritchie and Martin, 1999) there were determined the highest points of the scale“Need of Accurate Structurization of Work and Feedback” that demonstrated their responsible attitude to accurate realization of the goal as well as eagerness to satisfy the expectations. The second stage of the hierarchy was occupied by “Need of Interesting and Socially Beneficial Work” and “Need of High Salary and Financial Benefits”. The proximity of indicators concerning those indicators showed that for servicemen of the NGU socially beneficial work considered to be the source of income. The next stage was occupied by “Need of Posing Brave and Tough Goals and of Achieving them”, “Need of Obtaining the Recognition by Other People”, “Need of Self-Improvement and Development as Personality” which characterized those servicemen as brave, ambitious, and desiring to develop people.

In accordance with “Sense-Bearing and Life Orientations” (Muzdybaiev, 1998) servicemen of group HE had one of the highest indicators of “Life Understanding”. They had significant prospects of life and one of the highest indicators concerning the scale “Locus of Control-I” and “Locus of Life Control”.

During the use of the method “Locus of Control” (Ksienofontova, 1999) servicemen of group HE had the highest indicators of internality among all the compared groups: “General Internality”, “Internality in the Sphere of Achievements”, “Internality in the Sphere of Professional Activity”, “Internality in Interpersonal Communication”. Furthermore, they had high indicators of the scale “Internality in the Sphere of Health”, “Readiness for Activities which was Connected with Difficulties Overcoming”, “Readiness for Self-Planning”. This group had the lowest indicator of a return scale “Negation of Activity”. Servicemen of this group did not eager to shift the blame of fails on others “Internality in the Sphere of Fails”.

Due to the method of “Will-Regulated Personality” (Hutkin and Mikhalchenko, 2000) members of group HE also had one of the highest indicators they conceded only before group MLE1. The highest indicators of group HE were “Perseverance”, “Determination” and “Self-Control”. The lowest indicators were “Self-Reliance” and “Organization of Activity”. The latest indicators were the highest among the compared groups and had sufficient level of development.

The less effective group was distinguished on the basis of other significantly high indicators ofthe method which described the motivation. Thus, due to the data of“Close Questionnaire of Examining the Motivation of Professional Choice Made by Applicants of the Ministry of Internal Affairs” (Moskalienko, 2002) the participants of group WE differed from all other groups on statistically significant level. The exceptions were the indicators of group MLE1 in the scale “Motives Related to Objective Socially Posed Tasks and to Content of Profession”, “Motives Related to External Prestigious Professions and Financial Welfare” and the lowest and minimal indicators were presented by the scales “Dependent Profession Selection”, “Antisocial Motives”. This data demonstrated thepassion of those servicemen and their high emotionality.

To the core of “Methods of Studying the Motivational Profile of Personality” (Ritchie and Martin, 1999) there was incorporated the mechanism of overcoming social eagerness to get answers. It gave more information concerning the hierarchy of motives of this group; however, the distance from the most significant motive to the least significant stayed the shortest among all the compared groups. The most expressed motives of this group as well as in group HE of servicemen were “Need of Accurate Structurization of Work and Feedback”, but the next stage was occupied by motives which described comfortable conditions of work including normal circle of communication: “Need of Forming and Supporting Long-Term Stable Relations”, “Need of High Working Conditions and Comfortable Surrounding”, “Need of Diversity, Breaks and Stimulations, Eagerness to Avoid Everyday Routine”. The least important in that group were the motives which described the interest in society: “Need of Obtaining the Recognition by Other People”, “Need of Interesting and Socially Beneficial Work”, “Need of Manipulation and Power, Eagerness to Control the Other People”, “Need of Social Relations”.

According to the data proposed by “Sense-Bearing and Life Orientations” (Muzdybaiev, 1998) the participants of group WE had middle indicators of life overthinking and control localization (that level was higher than in groups MWE, MHE, and MLE2 and lower than in groups MLE1 and HE). Peculiarities of this group were in concentration on “Life Process”, in accordance with this scale there were distinguished the highest indicators among all the compared groups.

Moreover, there was a need to highlight the indicators of group WE concerningthe method of "Locus of Control" (Ksienofontova, 1999) and their combination with indicators on the method "Will-Regulated Personality" (Hutkin and Mikhalchenko, 2000). Thus, on the "General Scale" those servicemen with low efficiency had one of the highest indicators giving priority only to group HE. That showed absolute connection between their "I" and motives including desires and needs. However, the scale "Readiness for Difficulties Overcoming" demonstrated the lowest indicators among all the distinguished groups.

Participants of this group had one of the lowest indicators of the scale "Will-Regulated Personality", they gave priority only to group MLE2. Among all the compared groups the least effective servicemen had the lowest indicators of the scale "Self-Reliance" that way they developed the dichotomywith highly effective servicemen whose indicators of this scale were the highest among all the groups.

Participants of group WE as well as of MLE1 had the highest points of the scale "Close Questionnaire of Examining the Motivation of Professional Choice Made by Applicants of the Ministry of Internal Affairs" (Moskalienko, 2002). However, the hierarchy of motives of choosing the profession in group MLE1 differed from group WE. The most expressed and significant in comparison with other groupswere the "Motives Related to Objective Socially Posed Tasks and to Content of Profession". The next hierarchy stage was developed by three types of motives which were marked with the eagerness of self-regulation: "Independent Profession Selection", "Motives Related to Eagerness of Compensation of Temper Flaws" and "Motives Related to Personal and Professional Development".

"Motivational Profile of Personality" of this group was built around the vector: "Need of High Salary and Financial Benefits", "Need of Manipulation and Power, Eagerness to Control the Other People". That characterized those servicemen as performers, so called "employee".

The second hierarchy stage was formed by: "Need of Accurate Structurization of Work and Feedback", "Need of Obtaining the Recognition by Other People". Such a high position of desire to be recognized highlighted this group among all the other groups.

The third stage was developed with the help of the following motives: "Need of Self-Improvement and Development as Personality", "Need of Interesting and Socially Beneficial Work". Their combination demonstrated the importance of professional honour for those servicemen.

Specific stage was occupied by the motives of social cooperation "Need of Social Relations", "Need of Forming and Supporting Long-Term Stable Relations". Indicators of the scale "Need of Social Relations" of this group were the highest among all the compared groups (differences reached the level of statistic importance and tendency to these motives with other groups except group HE).

The next stage included four types of motives due to which servicemen of group MLE1 had the lowest indicators among all the compared groups: "Need of Posing Brave and Tough Goals and of Achieving Them" – 28.98±4.11, "Need of Being Creative, Thoughtful, and Open for Further Ideas Employee", "Need of High Working Conditions and Comfortable Surrounding", and "Need of Diversity, Breaks and Stimulations, Eagerness to Avoid Everyday Routine".

The peculiarities of group MLE1 included incredibly high indicators of the general scale "Sense-Bearing and Life Orientations" which statistically differed from other groups. Sense of life in this group was focused on the future – those servicemen had the highest indicators of the scale "Goal". However, group MLE1 had the highest indicators among all the compared groups of the scale "Result" that highlighted the importance of recognizing their achievements by the participants.

Group MLE1 had an interesting combination of scales "Locus of Control" and "Will Regulation". Thus, group MLE1 had the highest indicators among all the compared groups of both scales of locus of control method of "Sense-Bearing and Life Orientations" (Muzdybaiev, 1998): "Locus of Control – I", "Locus of Control – Life". Although, according to the method"Locus of Control" in group MLE1 there were one of the lowest indicators of the general scale and according to the scales which differentiated that indicator: "Internality in Thoughts about Life in General", "Professional and Processual Aspects of Internality", "Responsibility in the Sphere of Interpersonal Relations", "Readiness for Self-Planning", and "Internality in the Sphere of Fails".

According to all the scales "Will-Regulated Personality" the servicemen of group MLE 1 had the highest points. The exception was made by the scale "Self-Reliance" which was the highest in group HE. Among the components of will regulation of servicemen from group MLE1 the most expressed were: "Perseverance" and "Determination". The least expressed indicators were: "Self-Reliance" and "Organization of Activity".

Such combination demonstrated the executive motivation in the sphere of professional activity and cooperation concerning the conscious perception of the role of “a hard-working performer”. Servicemen of group MLE1 realized their actions and were able to overcome difficulties to achieve the posed goals, they trusted the decisions of their commanders, and they were assured in their actions that gave them the possibility to express determination.

Group MLE1 also had the highest points of the indicator “Insincerity” that did not demonstratethe insincerity, but their being orientated on socially approved “correct” answer on the commander’s claims.

Participants of group MLE2 were the only individuals whose motives connected with socially posed goals and with the content of profession were not leading during the military profession selection. Other peculiarities included slight differentiated motives of profession selection. Thus, the most highlighted were: “Motives Related to Personal and Professional Development”, “Motives Related to Eagerness of Compensation of Temper Flaws”. The least expressed were motives “Dependent Profession Selection”. The second stage was occupied by “Motives Related to Objective Socially Posed Tasks and to Content of Profession”. Penultimate stage was obtained by “Motives Related to Romanticization of Profession”, “Independent Profession Selection”, and “Antisocial Motives”. Nevertheless, romantic and antisocial motives were significantly higher than in other compared groups, but they gave priority only to the indicators of group WE.

Received indicators of the method “Motivational Profile of Personality” (Ritchie and Martin, 1999) were protected from the effects’ activity which negatively influenced the differentiation of motives. According to the data of this method group MLE2 had the following significant indicators: “Need of High Salary and Financial Benefits”. The least expressed and lagged indicators were “Need of Interesting and Socially Beneficial Work”. Motivational vector, which they developed, depicted their expressive, useful, and selfish direction.

The second stage in hierarchy of motives was occupied by “Need of Obtaining the Recognition by Other People”, “Need of Accurate Structurization of Work and Feedback”. The data represented by the scale “Need of Obtaining the Recognition by Other People” showed that on statistical level servicemen of group MLE2 differed from other groups except group MLE1 with which they had almost identical indicators.

The next stage in hierarchy of motives “Need of Being Creative, Thoughtful, and Open for further Ideas Employee”, “Need of Posing Brave and Tough Goals and of Achieving them”, and “Need of High Working Conditions and Comfortable Surrounding”. Group MLE2 had one of the highest indicators of “Need of Being Creative, Thoughtful, and Open for Further Ideas Employee” due to which on statistic level they differed from all other groups except group WE.

On the next stage there was a combination of “Need of Forming and Supporting Long-Term Stable Relations” and “Need of Self-Improvement and Development as Personality” which demonstrated definite benefits of relations. Servicemen of group MLE2 wanted to choose the surrounding which could help their development.

The next stage was occupied by “Need of Social Relations”, “Need of Diversity, Breaks and Stimulations, Eagerness to Avoid Everyday Routine”, it determined that social relations were used by the participants of group MLE2 for fun, rest, and spare time spending.

Servicemen of group MLE2 had the lowest indicators among all the compared groups on the scales of the method “Sense-Bearing and Life Orientations”. Despite that, the indicators of this group on the scale “Goal” were and “Process”, those results were almost identical that demonstrated their orientation on the nearest future.

Group MLE2 among the other groups washighlighted with the highest indicator of the scale “Negation of Activity” that demonstrated the confidence in futility of eagerness to achieve the goals of life.

Moreover, group MLE2 had the lowest indicators of all the scales of the method “Will-Regulated Personality” among all the compared groups. Extremely low indicators were inthe scale “Self-Reliance”.

Indicators of the motivation of choosing the military profession in group MHE were weakly expressed in the scale of the method “Close Questionnaire of Examining the Motivation of Professional Choice Made by Applicants of the Ministry of Internal Affairs”. The motives which were diagnosed with the help of this method developed the vector from “Dependent Profession Selection”, “Antisocial Motives” to “Motives Related to Objective Socially Posed Tasks and to Content of Profession”. The second stage in hierarchy of motives of profession selection showed the struggle for professional development in the past: “Motives Related to Eagerness of Compensation of Temper Flaws”, “Motives Related to Personal and Professional Development” and “Motives Related to External Prestigious Professions and Financial Welfare”.

Due to the “Methods of Studying the Motivational Profile of Personality” (Ritchie and Martin, 1999) the group MHE had the most expressed indicators which made them significantly different from others in “Need of High Salary and Financial Benefits" and the least expressed were indicators of "Need of Manipulation and Power, Eagerness to Control the Other People".

The second stage in hierarchy of motives was occupied by "Need of Interesting and Socially Beneficial Work", "Need of High Working Conditions and Comfortable Surrounding", "Need of Accurate Structurization of Work and Feedback". Then there were motives which demonstrated their ambitions "Need of Obtaining the Recognition by Other People", "Need of Self-Improvement and Development as Personality".

Less important for group MHE were the motives which described the eagerness to get new and non-standard issues in their work: "Need of Posing Brave and Tough Goals and of Achieving Them", "Need of Diversity, Breaks and Stimulations, Eagerness to Avoid Everyday Routine", and "Need of Being Creative, Thoughtful, and Open for further Ideas Employee". Even less important for them was the desire to be engaged into social cooperation: "Need of Forming and Supporting Long-Term Stable Relations", "Need of Social Relations".

Due to the scales of the method "Sense-Bearing and Life Orientations" (Muzdubaiev, 1998) servicemen of group MHE had statistically lower indicators than groups HE and MLE1, but higher than group MLE2. Besides that, they as well as the mentioned groups had almost identical indicators of the scales "Goal" and "Process". There was not any increase of the scale "Result".

Due to the indicators of the method "Locus of Control" (Ksenofontova, 1999) servicemen of group MHE had identically low quantity of general points as well as groups MLE1 and MLE2. The peculiarities of group MHE included the lowest indicators among all the compared groups "Internality in the Sphere of Professional Activity" which were formed because of weak indicators "Professional and Social Aspect of Internality". Moreover, other indicators related to the control in cooperation were decreased "Internality in Interpersonal Communication", "Competence in the Sphere of Interpersonal Relations" and "Responsibility in the Sphere of Interpersonal Relations".

In accordance with the data of the method "Will-Regulated Personality" (Hutkin and Mikhalchenko, 2000) servicemen of group MHE had indicators which were maximally close to group WE. However, their indicators of scales were weakly differentiated that did not demonstrate any urgency of will regulation, they substituted it with postarbitrary activity to make professional activities automatic.

Servicemen of group MHE had the lowest indicator of "Insincerity" that showed not only the desire to give completely honest answers, but also demonstrated slightly weaker social tolerance and communicative correctness.

In the structure of motivation of choosing the military profession group MWE had the most expressed motives such as: "Motives Related to Objective Socially Posed Tasks and to Content of Profession". Close to them there were "Motives Related to Eagerness of Compensation of Temper Flaws". Further there occurred "Motives Related to Personal and Professional Development" and "Motives Related to External Prestigious Professions and Financial Welfare". On the other side of hierarchy there were Dependent Profession Selection", "Antisocial Motives", "Motives Related to Romanticization of Profession". In group MWE intermediate position between values and motives which depreciated was occupied by the motives "Independent Profession Selection".

The participants of group MWE came close to the indicators of group HE: "Motives Related to Objective Socially Posed Tasks and to Content of Profession", "Motives Related to Personal and Professional Development". According to the scales "Dependent Profession Selection", "Motives Related to External Prestigious Professions and Financial Welfare", "Motives Related to Romanticization of Profession" and "Antisocial Motives" participants of group MWE moved closer to group MLE1.

Due to the data presented by the "Methods of Studying the Motivational Profile of Personality" (Ritchie and Martin, 1999) group MWE had the most expressed indicators of "Need of Accurate Structurization of Work and Feedback", "Need of High Salary and Financial Benefits". The next dense group of motives revealed in group MWE the urgency of needs of improving social status with their own powers "Need of Obtaining the Recognition by Other People", "Need of Self-Improvement and Development as Personality" and "Need of Interesting and Socially Beneficial Work".

The eagerness to change life for better and to make it more comfortable distinguished the place in hierarchy of motives of group MWE due to results received from the scales: "Need of High Working Conditions and Comfortable Surrounding", "Need of Posing Brave and Tough Goals and of Achieving Them".

Group MWE was quite low in hierarchy of motives "Need of Diversity, Breaks and Stimulations, Eagerness to Avoid Everyday Routine", "Need of Being Creative, Thoughtful, and Open for further Ideas Employee".

Less important for group MWE were indicators of "Need of Forming and Supporting Long-Term Stable Relations", "Need of Social Relations” and “Need of Manipulation and Power, Eagerness to Control the Other People” that demonstrated the eagerness to avoid social relations.
